ABOUT COVER
Peer Reviewer of World Journal of Methodology, Nikhil Sivnand, MBBS, MS, Fellowship in Basic Otology, Assistant Professor, Department of Otorhinolaryngology, Mahatma Gandhi Medical College and Research Institute, Sri Balaji Vidyapeeth, Puducherry 607402, India. nikhilsivanand@mgmcri.ac.in

AIMS AND SCOPE
The primary aim of World Journal of Methodology (WJM, World J Methodol) is to provide scholars and readers from various fields of methodology with a platform to publish high-quality basic and clinical research articles and communicate their research findings online.

WJM mainly publishes articles reporting research results obtained in the field of methodology and covering a wide range of topics including breath tests, cardiac imaging techniques, clinical laboratory techniques, diagnostic self-evaluation, cardiovascular diagnostic techniques, digestive system diagnostic techniques, endocrine diagnostic techniques, neurological diagnostic techniques, obstetrical and gynecological diagnostic techniques, ophthalmological diagnostic techniques, otological diagnostic techniques, radioisotope diagnostic techniques, respiratory system diagnostic techniques, surgical diagnostic techniques, etc.

INDEXING/ABSTRACTING
The WJM is now abstracted and indexed in PubMed, PubMed Central, Reference Citation Analysis, China National Knowledge Infrastructure, China Science and Technology Journal Database, and Superstar Journals Database.

RESPONSIBLE EDITORS FOR THIS ISSUE
Production Editor: Wen-Wen Qi; Production Department Director: Xiang Li; Editorial Office Director: Ji-Hong Liu.

Lutetium in prostate cancer: Reconstruction of patient-level data from published trials and generation of a multi-trial Kaplan-Meier curve

Andrea Messori

**Abstract**

**BACKGROUND**
Lutetium has been shown to be an important potential innovation in pre-treated metastatic castration-resistant prostate cancer. Two clinical trials have evaluated lutetium thus far (therap and vision with 99 and 385 patients, respectively), but their results are discordant.

**AIM**
To synthetize the available evidence on the effectiveness of lutetium in pre-treated metastatic castration-resistant prostate cancer; and to test the application of a new artificial intelligence technique that synthetizes effectiveness based on reconstructed patient-level data.

**METHODS**
We employed a new artificial intelligence method (shiny method) to pool the survival data of these two trials and evaluate to what extent the lutetium cohorts differed from one another. The shiny technique employs an original reconstruction of individual patient data from the Kaplan-Meier curves. The progression-free survival graphs of the two lutetium cohorts were analyzed and compared.

**RESULTS**
The hazard ratio estimated was in favor of the vision trial; the difference was statistically significant ($P < 0.001$). These results indicate that further studies on lutetium are needed because the survival data of the two trials published thus far are conflicting.

**CONCLUSION**
Our study confirms the feasibility of reconstructing patient-level data from...
survival graphs in order to generate a survival statistics.

**Key Words:** Survival analysis; Individual patient data reconstruction; Kaplan-Meier curves; Meta-analysis; Prostate Cancer; Lutetium

**Core Tip:** This paper describes the application of a new technique of individual-patient data reconstruction to the progression-free survival curves published in two trials evaluating lutetium in metastatic prostate cancer. Our analysis interpreted these survival data and showed discordant results between the two trials, that need to be addressed by further clinical research.

**INTRODUCTION**

Lutetium has been shown to be an important potential innovation in pre-treated metastatic prostate cancer, but the extent to which outcomes are improved by this treatment still needs to a fully investigated. Three studies have evaluated lutetium in this disease condition. One was phase II (therap trial[1]), the second was phase III (vision trial[2]); the third, which was an observational real-world study[3], differed from the first two because lutetium was given after radium-223.

In recent times, techniques that reconstruct individual patient data from the graphs of Kaplan-Meier curves have considerably improved in terms of performance and easy applicability[4]. One advantage is that the availability of these techniques permits to combine multiple survival curves published in different trials without using any meta-analytical statistics. An example of this approach is presented herein. Our objective was two-fold: 1) to quantify the gain in progression-free survival determined by lutetium; 2) to demonstrate the applicability of techniques of patient-level data reconstruction in addressing specific questions based on time-to-event endpoints without the need to employ any meta-analytic statistics.

**MATERIALS AND METHODS**

We applied the shiny technique of individual patient data reconstruction[4] to the Kaplan-Meier graphs of progression-free survival reported in the therap phase-II trial[1] and in the vision phase III trial[2]. Both trials were conducted in patients with metastatic castration-resistant prostate cancer previously treated for their metastatic disease. In the therap trial, the treatment group received Lu-PSMA-617 (6.0–8.5 GBq intravenously every 6 wk for up to six cycles) while the controls were given cabazitaxel (20 mg/m² intravenously every 3 wk for up to ten cycles). In the vision trial, the treatment group received 177Lu-PSMA-617 (7.4 GBq every 6 wk for four to six cycles) plus protocol-permitted standard care while the controls received standard care alone. In the therap trial, progression-free survival was defined as the interval from randomisation to first evidence of pupil-size artefact progression defined by an increase of at least 25% and at least 2 ng/mL after 12 wk (as per PCWG3[16]), radiographic progression using locally reported computed tomography and bone scanning [Response Evaluation Criteria In Solid Tumors (RECIST) 1.1 and PCWG3 criteria for bone lesions], commencement of non-protocol anticancer treatment, or death from any cause. In the vision trial, the end-point was image based progression free survival.

The progression-free survival graphs of the two lutetium cohorts by Hofman et al[1] for the therap trial (99 patients; follow-up of 18 mo; 90 events) and Sartor et al[2] for the vision trial (385 patients; follow-up of 30 mo; 254 events). For each of these two Kaplan-Meier curves, the graph was digitalized and converted into x-y data pairs using Webplotdigitizer (version 4.5, https://apps.automeris.io/wpd/). Then, the shiny package (version: 1.2.2.0; subprogram “Reconstruct Individual Patient Data”; https://www.trialdesign.org/one-page-shell.html#IPDfromKM, see reference[4]) was used to reconstruct patient-level data on the basis of x-y data pairs, total number of enrolled patients, and total number of events. Finally, the pooled survival curves were generated from the reconstructed patient-level data and analyzed through standard Cox statistics. For this purpose we used three packages
two trials published thus far demonstrate quite conflicting results. The example described in this paper

receptor–pathway inhibitor and one or two taxane regimens and had PSMA-positive gallium-68
metastatic castration-resistant prostate cancer previously treated with at least one androgen-
treatment with androgen receptor-directed therapy was allowed. In the vision trial, patients had
patients given lutetium in the therap trial with the 385 patients given lutetium in the vision trial.
Figure 1 shows the two Kaplan-Meier curves generated from reconstructed patient-level data. The
HR estimated from these curves favored the patients of the vision trial and was 0.59 (95%CI, 0.46 to 0.75). The difference was statistically significant (P < 0.001).

DISCUSSION
When two or more randomised trials are available on a therapeutic issue and the clinical end-point is
the form of time-to-event, synthesising the clinical evidence is a complex issue, and there is presently no
consensus on which methodological approach should be preferred[5,6]. Pooling the values of HR is
certainly the method most commonly used, but its important limitations have been widely recognised
for many years (eg. the inability to account for the length of follow-up, the inability to model variations
of risk over time, the dimensionless nature of HR as opposed to the greater informative value of
absolute parameters such as medians, etc.)[5]. The development of the restricted mean survival time has
represented an advancement in this field[8,9], but the use of this parameter unfortunately remains low.
In this context, the marked improvement in performance of techniques that reconstruct individual-
patient data[4] represents an important innovation, the role of which still needs to be fully evaluated.
On the one hand, reconstructing individual-patient data is a mandatory pre-requisite to determine the
RMST, and this explains the increased use of these reconstruction techniques when a single trial needs
to be analysed[7]. On the other hand, another potential use of these techniques is being recognised when
multiple trials are available: in such cases, these techniques offer a new methodological alternative to
standard meta-analytic methods[5,6] and also to the more recent approaches where meta-analysis is
based on the use of RMSTs[8,9].
The various parameters mentioned above (especially HR, RMST, and median) have been investigated
for many years to identify their respective advantages and disadvantages, and the literature on this
issue is wide[7]. In contrast, the literature on the use of reconstructed survival curves is still in its early
stages[4,6], and this holds true particularly when multiple trials are analysed and pooled together.
The experience described herein offers a limited but useful contribution to the development of meta-
analysis-like methods based on reconstructed survival curves.
The two control groups of the two trials differed in the treatment they received, and so were not included in our analysis, which was focused only on the two lutetium groups of the two trials. In
comparing these two group with one another, our results raise the need to explain the statistically
different outcomes shown by the HR and presented in Figure 1.
The inclusion criteria of the therap and vision trials were very similar, and so they likely had no
substantial role in determining this difference. In fact, in the therap trial, patients had metastatic
castration-resistant cancer and PET eligibility criteria for the trial were PSMA-positive disease, and no
sites of metastatic disease with discordant FDG-positive and PSMA-negative findings; previous
treatment with androgen receptor-directed therapy was allowed. In the vision trial, patients had
metastatic castration-resistant prostate cancer previously treated with at least one androgen-
receptor–pathway inhibitor and one or two taxane regimens and had PSMA-positive gallium-68
(68Ga)–labeled PSMA-11 and PET scans. While these differences in the inclusion criteria do not seem to
suggest a better prognosis for patients included in either trial, a number of factors (eg. environmental
and lifestyle factors, tissue biomarkers, molecular pathological epidemiology, the microbiota, etc.) might
have influenced tumor development and response to therapy. Hence, the discrepancies observed across
the two trials included in our analysis might be explained by these factors. As regards innovative
treatments such as lutetium, it should be stressed that molecular pathological epidemiology research
has a growing role and is increasingly recognized to be a promising strategy to improve prediction of
response to therapy.
In summary, the main strength of our analysis lies in the originality of the methodological approach
that reflects the recent availability of very efficient patient data reconstruction techniques. The main
limitation is represented by the indirect nature of the comparison between the two lutetium cohorts.

CONCLUSION
Our study indicates that further studies on Lu-PSMA-617 are needed because the survival data of the
two trials published thus far demonstrate quite conflicting results. The example described in this paper
Figure 1 Kaplan-Meier curves from reconstructed patient-level data. Pooled Kaplan-Meier survival curves obtained by reconstruction of individual patient data from two trials [therap] and [vision]. Vision trial in red, therap trial in blue; time expressed in months. See text for details.

confirms the feasibility of reconstructing patient-level data from survival graphs in order to generate a survival statistics from these reconstructed data. To evaluate the advantages and disadvantages of this new methodological approach, further analyses will be needed.

ARTICLE HIGHLIGHTS

Research background
Two trials have been published to assess the effectiveness of lutetium in metastatic prostate cancer. The need to convert these effectiveness data into a pooled estimate represents a useful opportunity to test an innovative technique of individual patient reconstruction based on the analysis of Kaplan-Meier curves (shiny method).

Research motivation
The main motivation was to test the performance of the shiny method based on a real data-set.

Research objectives
Clarifying the effectiveness of lutetium in metastatic prostate cancer and confirm the reliability of the shiny method as a tool for reconstructing individual patient data.

Research methods
The clinical trials that have thus far evaluated lutetium in metastatic prostate cancer have been identified by standard literature search. A pooled survival curve has been generated from these trials by using the shiny technique of individual patient data reconstruction.
Research results
Two clinical trials were identified. A pooled Kaplan-Meier survival curve was generated that synthesizes the current evidence on the effectiveness of this treatment in this disease condition.

Research conclusions
A two-fold conclusion: First, lutetium is effective in metastatic prostate cancer; second, the Shiny technique can successfully be used to pool survival data from two trials without employing any meta-analytical method.

Research perspectives
The shiny technique has been confirmed to be a useful new tool for analyzing survival data from multiple trials and therefore deserves to be further applied in the analysis of clinical evidence.
