ABOUT COVER

Peer-reviewer of World Journal of Clinical Cases, Prof. Adrián Ángel Inchauspe, obtained his MD in 1986 from La Plata National University (Argentina), where he remained as Professor of Surgery. Study abroad, at the Aachen and Tubingen Universities in Germany in 1991, led to his certification in laparoscopic surgery, and at the Louis Pasteur University in Strasbourg France, led to his being awarded the Argentine National Invention Award in 1998 for his graduate work in tele-surgery. He currently serves as teacher in the Argentine Acupuncture Society, as Invited Foreigner Professor at the China National Academy of Sciences and Hainan Medical University, and as editorial member and reviewer for many internationally renowned journals. (L-Editor: Filipodia)

AIMS AND SCOPE

The primary aim of World Journal of Clinical Cases (WJCC, World J Clin Cases) is to provide scholars and readers from various fields of clinical medicine with a platform to publish high-quality clinical research articles and communicate their research findings online.

WJCC mainly publishes articles reporting research results and findings obtained in the field of clinical medicine and covering a wide range of topics, including case control studies, retrospective cohort studies, retrospective studies, clinical trials studies, observational studies, prospective studies, randomized controlled trials, randomized clinical trials, systematic reviews, meta-analysis, and case reports.

INDEXING/ABSTRACTING

The WJCC is now indexed in Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports/Science Edition, PubMed, and PubMed Central. The 2020 Edition of Journal Citation Reports® cites the 2019 impact factor (IF) for WJCC as 1.013; IF without journal self cites: 0.991; Ranking: 120 among 165 journals in medicine, general and internal; and Quartile category: Q3.

Resorption of upwardly displaced lumbar disk herniation after nonsurgical treatment: A case report

Yi Wang, Shi-Chuan Liao, Guo-Gang Dai, Ling Jiang

BACKGROUND
The spontaneous resorption of lumbar disk herniations (LDHs) has been widely reported. However, the majority of these reports analyze the resorption of LDHs that were displaced backwards or downwards. There have been few reports on the spontaneous resorption of upwardly displaced L4/5 LDH that has caused femoral nerve symptoms.

CASE SUMMARY
A 55-year-old woman presented to our hospital with acute pain in her left leg. She had been suffering from recurrent lower back pain for approximately 1 year and began to feel pain accompanied with numbness at the anterior aspect of her left leg 7 d previously. On examination, a typical L4 nerve stimulation was noted. An upwardly displaced LDH at the L4/5 level was revealed by magnetic resonance imaging. The patient attained complete relief of her symptoms after 10 wk of nonsurgical treatment and the upwardly displaced herniation almost entirely disappeared. There was no recurrence during a follow-up of 2 years.

CONCLUSION
Clinicians should be aware that the nerves disturbed by LDHs vary according to the direction of the herniations and the probable resorption of upwardly displaced LDHs should be considered before making a decision on surgery.

Key Words: Lumbar disk herniation; Upward displacement; Resorption; Neurology; Rehabilitation; Case report

Core Tip: This is the first report of the spontaneous resorption of upwardly displaced L4/5 lumbar disk herniation that caused femoral nerve symptoms. No secular trends in the incidence of resorption were identified in the literature review.

INTRODUCTION

Lumbar disc herniation (LDH) can be treated non-surgically or surgically[1,2]. Resorption of LDH is one of the primary factors that contributes to relief following nonsurgical treatments; and thus has clinical significance in the nonsurgical treatment of LDH. The spontaneous resorption of LDHs has been widely reported[3-16]. However, the majority of these reports analyze the resorption of LDHs that were displaced backwards or downwards in the form of sequestration, extrusion, protrusion, or bulging[17]. The natural history of upwardly displaced LDHs has rarely been documented. In addition, upwardly migrated LDHs may exhibit a different pattern in disturbing nerve roots compared with LDHs displaced backwards or downwards. Therefore, we present this case study to demonstrate the femoral nerve symptoms that result from upwardly displaced L4/5 LDHs and provide an example of the spontaneous resorption of an upwardly displaced L4/5 LDH.

CASE PRESENTATION

Chief complaints
A 55-year-old woman presented to our hospital with acute pain in her left leg for 7 d.

History of present illness
The patient had been suffering from recurrent low back pain for approximately 1 year, and her pain was relieved spontaneously or after nonsurgical treatment. She began to feel pain accompanied by numbness at the anterior aspect of her left leg 7 d before presentation.

History of past illness
The patient underwent appendectomy for appendicitis 15 years ago.

Physical examination
Clinical examination revealed the following: a negative Lasegue’s sign and a positive femoral nerve stretch test of her left leg, hyposthesia over the distribution of the left femoral nerve, and normal muscle strength and deep tendon reflexes of her legs with a bilateral negative Babinski’s sign. She perceived an electric shock-like sensation in her left leg prompted by lumbar spine extension.

Laboratory examinations
Routine blood, blood biochemistry, serum C-reactive protein level and erythrocyte sedimentation rate were normal.

Imaging examinations
An upwardly displaced LDH at the L4/5 level was revealed by magnetic resonance imaging (MRI) (Figure 1).
Figure 1 Magnetic resonance imaging obtained at the patient’s initial visit. A: Sagittal T2-weighted magnetic resonance imaging revealed an L4/5 lumbar disk herniation moved upward to above the L4/5 disc level, lying behind the L4 vertebral body; B and C: Axial T2-weighted magnetic resonance imaging revealed that the lumbar disk herniation compressed the L4 nerve root at the left posterolateral of the L4 vertebral body.

FINAL DIAGNOSIS
The patient was diagnosed with an upwardly displaced L4/5 LDH.

TREATMENT
The patient received nonsurgical treatment with Traditional Chinese Medicine for 4 wk, which included bed rest, acupuncture, massage, moxibustion and Chinese medicine fumigation. All of her symptoms were relieved except for moderate lumbago, and she was discharged from the hospital. She underwent a follow-up visit every 2 wk and performed home-based exercise therapy following the doctor’s instructions for 6 wk.

OUTCOME AND FOLLOW-UP
She attained complete relief of her symptoms 10 wk after presentation. The upwardly displaced herniation mostly disappeared on the second MRI, which was performed 10 wk after her initial visit (Figure 2). There was no recurrence during a follow-up of 2 years, and only a small amount of herniated disc tissue was found on the third MRI, which was performed 2 years after the patient’s initial visit (Figure 3).

DISCUSSION
The resorption of LDHs after nonsurgical treatments has been widely reported since the first case in 1984. In these reports, the LDHs were characterized as decreasing or disappearing over time, and the nonsurgical treatments in these reports included bed rest, lumbar support, analgesics, oral steroids, non-steroidal anti-inflammatory drugs, epidural steroid injection, caudal epidural injections of local anesthetic, manipulation, hot back, ultrasound, electrotherapy, traction, exercises, Traditional Chinese Medicine and integrative Korean medicine[^3-16]. However, which of these treatments are essential for promoting resorption and the time when resorption takes place remains unclear.

The incidence of resorption varies in the existing reports depending on the different follow-up times. Lee reported the highest incidence of resorption of 96% with an average follow-up time of 341.38 ± 306.83 d[^3]. Two studies reported no resorption with follow-ups of 45 d[^4] and 20 d[^5], suggesting that resorption should not be expected to occur too soon after nonsurgical treatments. The relationship between the incidence of resorption and the time of follow-up was not consistent in these studies, and no secular trends in the incidence of resorption were identified in these studies (Table 1).

A meta-analysis reported the overall incidence of resorption of LDHs to be 66.66% (95%CI: 55.12%-78.21%)[^18], and randomized controlled trials have confirmed that resorption is a widespread phenomenon in patients with LDHs[^7,12,19]. The North American Spine Society has suggested that the probability of resorption should be

Figure 2  Magnetic resonance imaging obtained 10 wk after the patient’s initial visit. A: Sagittal T2-weighted magnetic resonance imaging revealed that most of the upwardly displaced disc material had disappeared; B and C: Axial T2-weighted magnetic resonance imaging revealed that a small amount of herniated disc material was visible at the left posterolateral of the L4 vertebral body and the L4/5 disc.

Figure 3  Magnetic resonance imaging obtained 2 years after the patient’s initial visit. A: Sagittal T2-weighted magnetic resonance imaging (MRI) revealed the upwardly displaced disc material had almost completely disappeared; B: Axial T2-weighted MRI revealed that a small amount of herniated disc material was visible at the left posterolateral of the L4 vertebral body; and C: Axial T2-weighted MRI revealed that the herniated disc material at the left posterolateral of the L4/5 disc had disappeared.
considered during the management of LDH\textsuperscript{[39]}. Although it is well known that sequestrated and large LDHs are more likely to undergo resorption\textsuperscript{[36-39]}, it is still not possible to accurately predict resorption in individual cases; even the possibility of resorption cannot be predicted for individual cases. Thus, for many cases that present without cauda equina syndrome or progressive neurological deficits, there remains no consensus on whether to perform surgical treatments or nonsurgical treatments\textsuperscript{[40]}. However, we cannot ignore the physical decompression that occurs during resorption of LDH, and the probability of resorption should be considered before making a decision on surgery.

The epidural space enlarges down the vertebral column\textsuperscript{[39]}. Thus, in the majority of cases, the LDH tends to protrude downward under the influence of gravity. Most of the existing studies reported resorption of backwardly or downwardly displaced LDHs, while upwardly displaced LDHs have been reported less. Macki et al\textsuperscript{[3]} reported a case of an upwardly migrated L4/5 LDH that was compressing the L5 nerve root and resorbed 5 mo after nonsurgical treatment. Another case presented the resorption of an upwardly migrated L4/5 LDH in a pregnant woman with sciatica\textsuperscript{[39]}. The upwardly displaced L4/5 LDHs of these two cases stimulated the L5 nerve root and resulted in sciatica.

There have been few reports on the spontaneous resorption of upwardly displaced L4/5 LDH that has caused femoral nerve symptoms. In most cases, LDH compresses the nerve root corresponding to the lower vertebral level; accordingly, L4/5 LDH disturbs the L5 nerve root, which originates at the L4/5 disc level and goes downward to the L5/S1 intervertebral foramen, subsequently causing sciatica. In rare cases, the L4/5 disc moves upward along the spinal canal to above the L4/5 disc level, and the herniated disc material is still connected to the L4/5 disc; hence, the herniation may disturb the L5 nerve root at the starting point at the L4/5 disc level or disturb the L4 nerve root, which originates at the L4 vertebral level and leaves the spinal canal above the L4/5 disc plane, or disturb both. In the present case, the herniated L4/5 disc moved upwards to the L4 vertebral level above the starting point of the L5 nerve root, similar to a prolapsed L3/4 disc, leading to compression of the L4 nerve root, which originates at the L4 vertebral level and results in femoral nerve symptoms. The upwardly displaced L4/5 LDH of this patient almost completely disappeared and was accompanied by complete relief of the femoral nerve symptoms 10 wk following nonsurgical treatment with Traditional Chinese Medicine.

Upwardly displaced LDHs are not very common. To our knowledge, this is the first report of the spontaneous resorption of upwardly displaced L4/5 LDH that has caused femoral nerve symptoms. This case also demonstrated that the nerves disturbed vary according to the direction of the herniation. Resorption of the upwardly displaced LDH in this case corresponds with existing reports on the resorption of LDHs.

**CONCLUSION**

The nonsurgical treatment of this patient was successful. Clinicians should be aware that the nerves disturbed by LDHs vary according to the direction of the herniation, and the probable resorption of upwardly displaced LDHs should be considered before making a decision on surgery. Future research should explore the relationship between resorption and time as well as methods for predicting resorption.
