Fatal arterial hemorrhage after pancreaticoduodenectomy: How do we simultaneously accomplish complete hemostasis and hepatic arterial flow?

Therapeutic strategy for arterial hemorrhage after PD

Abstract

BACKGROUND

Although arterial hemorrhage after pancreaticoduodenectomy (PD) is not frequent, it is fatal. Arterial hemorrhage is caused by pseudoaneurysm rupture, and the gastroduodenal artery stump and hepatic artery (HA) are frequent culprit vessels. Diagnostic procedures and imaging modalities are associated with certain difficulties. Simultaneous accomplishment of complete hemostasis and HA flow preservation is

europepmc.org/articles/PMC4412861

Mar 01, 2015 · Introduction. Resectional surgery for pancreatic cancer has advanced considerably in the last decade. The high mortality of nearly 25 % following pancreatoduodenectomy (PD) has now been reduced to less than 5 % [1–5] and even zero in some centres of excellence [6, 7]. However, the morbidity statistics **after** PD remain worrisome with a reported range of 25–50 % [6, 8–10].
