ABOUT COVER
Editorial Board Member of *World Journal of Clinical Cases*, Nicola Montemurro, MD, PhD, Assistant Professor, Consultant Physician-Scientist, Neurosurgeon, Surgeon, Surgical Oncologist, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa 56126, Italy. nicola.montemurro@unipi.it

AIMS AND SCOPE
The primary aim of *World Journal of Clinical Cases* (*WJCC, World J Clin Cases*) is to provide scholars and readers from various fields of clinical medicine with a platform to publish high-quality clinical research articles and communicate their research findings online.

*WJCC* mainly publishes articles reporting research results and findings obtained in the field of clinical medicine and covering a wide range of topics, including case control studies, retrospective cohort studies, retrospective studies, clinical trials studies, observational studies, prospective studies, randomized controlled trials, randomized clinical trials, systematic reviews, meta-analysis, and case reports.

INDEXING/ABSTRACTING
The *WJCC* is now indexed in Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports/Science Edition, Scopus, PubMed, and PubMed Central. The 2020 Edition of Journal Citation Reports® cites the 2019 impact factor (IF) for *WJCC* as 1.013; IF without journal self cites: 0.991; Ranking: 120 among 165 journals in medicine, general and internal; and Quartile category: Q3. The *WJCC*’s CiteScore for 2019 is 0.3 and Scopus CiteScore rank 2019: General Medicine is 394/529.

Incremental value of three-dimensional and contrast echocardiography in the evaluation of endocardial fibroelastosis and multiple cardiovascular thrombi: A case report

Li-Juan Sun, Ying Li, Wei Qiao, Jia-Hui Yu, Wei-Dong Ren

ORCID number: Li-Juan Sun 0000-0003-1825-9195; Ying Li 0000-0002-9189-3822; Wei Qiao 0000-0002-7921-7709; Jia-Hui Yu 0000-0003-0147-4948; Wei-Dong Ren 0000-0003-0273-0122.

Author contributions: Sun LJ and Li Y equally contributed to this work; Sun LJ, Li Y and Ren WD participated in the design of the study; Sun LJ and Yu JH collected clinical data; Ren WD, Qiao W and Li Y performed echocardiographic examinations and collected the images; Sun LJ wrote the manuscript; Ren WD revised the manuscript; all authors read and approved the final manuscript.

Supported by National Natural Science Foundation of China, No. 81571686.

Informed consent statement: Informed consent was obtained from the patient and the patient’s parents.

Conflict-of-interest statement: The authors declare that they have no conflicts of interest.

CARE Checklist (2016) statement: The authors have read the CARE Checklist (2016), and the manuscript was prepared and revised according to the CARE Checklist.

Abstract

BACKGROUND

Endocardial fibroelastosis (EFE) is a rare heart disease characterized by thickening of the endocardium caused by massive proliferation of collagenous and elastic tissue, usually leading to impaired cardiac function. Multimodality cardiovascular imaging for the evaluation of EFE with thrombi is even rarer.

CASE SUMMARY

We report a rare case of EFE associated with multiple cardiovascular thrombi. Three-dimensional (3D) and contrast echocardiography (CE) were used to assess ventricular thrombi. Anticoagulant therapy was administered to eliminate the thrombi. The peripheral contrast-enhanced thrombi with the highest risk were dissolved with anticoagulant therapy at the time of reexamination, which was consistent with the presumption of fresh loose thrombi.

CONCLUSION

This new echocardiography technique has a great advantage in the diagnosis and treatment of EFE. On the basis of conventional echocardiography, 3D echocardiography is used to display the position, shape, and narrow base of the thrombus. CE does not only help to confirm the diagnosis of thrombus, but also determines its risk.

Key Words: Endocardial fibroelastosis; Three-dimensional echocardiography; Contrast echocardiography; Thrombosis; Left ventricle; Case report

INTRODUCTION

Endocardial fibroelastosis (EFE) is a rare heart disease that frequently occurs in infants and children. It is characterized by diffuse thickening of the endocardium due to the proliferation of collagen and elastic fibers, presenting as unexplained heart failure. Patients with EFE are prone to endocardial thrombosis, which may be due to enlarged cardiac cavity, systolic dysfunction, and altered endothelium lining[1,2]. Previous studies have also reported that a thrombus can easily form in sites of akinetic, dyskinetic, or aneurysmal segments that were potentially at risk for thromboembolism[3]. If the embolus is detached from the mural thrombus, complications arise and other organ changes occur. Herein, we report a case of EFE with multiple thrombi of the left ventricle, abdominal aorta, renal artery, and common iliac artery diagnosed by multimodality cardiovascular imaging. The incremental role of three-dimensional (3D) and contrast echocardiography (CE) in the clinical diagnosis of thrombi is also explained.

CASE PRESENTATION

Chief complaints
An 11-year-old girl was admitted to Shengjing Hospital with nausea and vomiting for 4 d.

History of present illness
The patient developed nausea and vomiting 4 d ago and has vomited 1-2 times a day. Vomiting included the stomach content and was non-ejective. In order to achieve standardized treatment, the patient was admitted to the department of Pediatrics at Shengjing Hospital of China Medical University on June 1, 2020 with "endocardial elastic fiber hyperplasia and vomiting pending investigation".

History of past illness
Her medical history was significant for EFE diagnosed 10 years ago. She has been undergoing regular examinations and treatments for a decade, and her condition was relatively stable.

Physical examination
Physical examination showed that the liver margin was palpable 4 cm below the costal margin and 6 cm below the xiphoid process. Bilateral dorsal foot pulse was not detected.

Laboratory examinations
The positive results from laboratory tests were as follows: erythrocyte 5.0 × 10^{12}/L, hemoglobin 118 g/L, erythrocyte sedimentation rate 38 mm/h, urine protein quantification 1.41 g/L, 24 h urine protein quantification 1.41 g/d, uric acid 537 µmol/L, total protein 52.8 g/L, albumin 25.4 g/L, serum cystatin C 1.28 mg/L, interleukin-6 8.70 pg/mL, prothrombin time 17.1 s, prothrombin time activity 55%,
activated partial thromboplastin time 38 s, D-dimer 1258 µg/L, and fibrinogen degradation product 12.4 mg/L. Blood gas analysis revealed that the oxygen partial pressure was reduced to 43.5 mmHg.

**Imaging examinations**

Two-dimensional (2D) echocardiography revealed that the whole heart was significantly enlarged (left ventricular end-diastolic dimension of 67 mm), and left ventricular wall movement was generally significantly reduced with uncoordinated movement. The endocardium was thicker, about 2.4 mm at the thickest, and the echo was enhanced. Multiple mass images were observed in the left ventricle. There was a high-low mixed echo mass about 50 mm × 33 mm in size near the apex of the left ventricular lateral wall that was slightly deformed (Figure 1A). A mixed strong and weak echogenic mass 40 mm × 15 mm in size was also detected at the apex of the left ventricle with obvious activity and deformation. Its base was narrow and thin at about 1-2 mm (Figure 1B). Another 8 mm × 10 mm medium-high echo mass with obvious activity was detected at the apex of the heart (Figure 1B). Multiple trabeculations were detected at the apex of the left ventricle. Small amounts of regurgitation were detected in the mitral valve. The left ventricular systolic function was significantly reduced at rest with an ejection fraction of 28%.

3D echocardiography showed that a thrombus with a wide base and low mobility protruded from the side wall of the left ventricle (Figure 2A). A mobile thrombus component with a thin pedicle was protruding from the left ventricular apex (Figure 2B).

The CE results showed that the mass on the left ventricular lateral wall near the apex was relatively fixed and had slight activity and deformation, but there was contrast agent entering at a part of the junction between the base of the mass and the left ventricular wall. The other part of the base was tightly connected to the left ventricular wall. Its inner portion showed no contrast enhancement (Figure 3A). The masses in the left ventricular apex had great mobility and deformation. Contrast agent was detected in the peripheral part of these masses, while most of their center portions were not contrast-enhanced (Figure 3B). This mass was determined to be of the highest risk according to CE results. These masses were considered to be thrombi due to their echocardiographic morphological characteristics and the patient's primary disease.

The 3D computed tomography angiography demonstrated thromboembolism from the abdominal aorta (level of the right accessory renal artery) to the bilateral common iliac artery (Figure 4). Thrombosis was also detected in the proximal left renal artery and the opening of the right renal artery, with multiple ischemic foci in both kidneys.

Color Doppler ultrasonography revealed ischemic changes in the arterial spectrum of both lower limbs.

**FINAL DIAGNOSIS**

EFE with multiple thrombi of the left ventricle, abdominal aorta, renal artery, and common iliac artery.

**TREATMENT**

Anticoagulation and other symptomatic treatments were administered to eliminate the thrombus and relieve the patient's other symptoms.

**OUTCOME AND FOLLOW-UP**

After 5 d of anticoagulant treatment, the smallest thrombus at the apex of the left ventricle disappeared and the other thrombus became significantly smaller (from 40 mm × 15 mm to 3 mm × 4.5 mm). The change in the largest thrombus in the left ventricular lateral wall near the apex was not significant (from 50 mm × 33 mm × 17 mm to 50 mm × 22 mm × 18 mm). After 12 d of anticoagulation treatment, the active thrombus disappeared, and only the thrombus located in the left ventricular lateral wall near the apex was detected, the size of which was about 49 mm × 19 mm. Despite adequate medical measures, congestive heart failure did not improve completely, and after two months the patient eventually developed cardiogenic shock, respiratory
DISCUSSION

EFE is a rare heart disease characterized by thickening of the endocardium, cardiac enlargement, and myocardial dysfunction. The exact etiology of EFE is unknown and failure, sepsis, and severe pneumonia. Finally, the patient and her parents abandoned treatment and asked to be discharged. The timeline of information related to this case report is shown in Table 1.

3D: Three-dimensional; 2D: Two-dimensional.

Figure 4 Thromboembolism view from three-dimensional computed tomography angiography. Thrombosis was detected from the abdominal aorta to the bilateral common iliac arteries.

Traditional 2D echocardiography is the most convenient imaging method to evaluate the morphology and mobility of the mass due to its availability, versatility, and low cost. However, the accuracy of 2D echocardiography is limited because the mass calculations are based on geometric assumptions. Real-time 3D echocardiography provides a novel echocardiographic method to measure masses by directly observing the myocardial boundaries of the entire left ventricle. On the basis of 2D echocardiography diagnosis, 3D echocardiography comprehensively shows the position, shape, and narrow base of the mass. The 3D echocardiography is an accurate method for quantifying left ventricular mass. It is in better agreement with the reference value of cardiac magnetic resonance imaging (cMRI), which is considered to be the gold standard for quantifying left ventricular masses. It also has advantages over cMRI in its availability, rapid image acquisition, and processing, and in cases where the patient cannot access a cMRI scanner.

Using the combination of 3D echocardiography and CE, the mass can be displayed more accurately and vividly. We further performed CE to detect the nature, density, and connection to the left ventricular wall of the mass in order to make an accurate
Sun LJ et al. 3D and CE evaluate EFE with thrombi

CONCLUSION

The new echocardiography technique has a great advantage in the diagnosis and treatment of EFE. On the basis of conventional echocardiography, 3D echocardiography is used to display the position, shape, and narrow base of the thrombus. CE does not only help to confirm the diagnosis of the thrombus, but also determines its risk. The prognosis of EFE with left ventricular thrombus is generally poor.
