ABOUT COVER
Editorial Board of *World Journal of Gastroenterology*, Dr. Rosa Leonôra Salerno Soares is Full Professor at the Faculty of Medicine of Universidade Federal Fluminense (Niterói, Rio de Janeiro). She completed her doctorate in medicine at the Federal University of Rio de Janeiro in 1994 and post-doctorate training in 2009 at the University of Porto, Portugal. Her career experience in internal medicine and clinical research is founded upon her interests in medicine, gastroenterology, intestinal diseases, functional diseases of the gastrointestinal tract, and nutritional support. Her academic teaching pursuits encompass curriculums in applying the scientific methodology to the health field. Currently, she is Head of the Department of Clinical Medicine (MMC) of the Faculty of Medicine of Universidade Federal Fluminense. Her full curriculum vitae can be accessed at: http://lattes.cnpq.br/4236328959320774. (L-Editor: Filipodia)

AIMS AND SCOPE
The primary aim of *World Journal of Gastroenterology* (*WJG, World J Gastroenterol*) is to provide scholars and readers from various fields of gastroenterology and hepatology with a platform to publish high-quality basic and clinical research articles and communicate their research findings online. *WJG* mainly publishes articles reporting research results and findings obtained in the field of gastroenterology and hepatology and covering a wide range of topics including gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, gastrointestinal oncology, and pediatric gastroenterology.

INDEXING/ABSTRACTING
The *WJG* is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as ScicSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central, and Scopus. The 2020 edition of Journal Citation Report® cites the 2019 impact factor (IF) for *WJG* as 3.665; IF without journal self cites: 3.534; 5-year IF: 4.048; Ranking: 35 among 88 journals in gastroenterology and hepatology; and Quartile category: Q2.

RESPONSIBLE EDITORS FOR THIS ISSUE
Production Editor: Yan-Liang Zhang; Production Department Director: Yun-Xiaojian Wu; Editorial Office Director: Ze-Mao Gong.

Abstract

BACKGROUND

Endoscopy-based Kyoto classification for gastritis and pathological topographic distribution of neutrophil infiltration are correlated with gastric cancer risk.

AIM

To investigate the association between Kyoto classification and the topographic distribution of neutrophil activity.
INTRODUCTION

Stomach cancer is the third leading cause of cancer-related mortality in both sexes worldwide according to the 2018 GLOBOCAN estimates\(^1\). Thus, the key to obtaining a significant effect on the prognosis of gastric adenocarcinoma and its economic burden is to accurately identify at-risk individuals\(^2,4\).

The updated Sydney System is the most widely accepted method for the histological
classification and grading of gastritis\cite{12}; it can also assess pathologic features related to *Helicobacter pylori* (*H. pylori*) infection such as neutrophil activity, chronic inflammation, atrophy, intestinal metaplasia, and gastric cancer\cite{13}. Neutrophil activity is measured by continuing acute inflammation and is linked to tissue damage. The density of intraepithelial neutrophils is correlated with the extent of mucosal damage and intensity of *H. pylori* infection\cite{14,15}. The topographic distribution of neutrophil activity has been reportedly associated with gastric cancer development\cite{16}.

Endoscopy-led risk stratification is preferable since pathology-based evaluation is more invasive. The endoscopic Kyoto classification of gastritis was advocated by the Japan Gastroenterological Endoscopy Society in 2013. The Kyoto classification was established with the aim to unify the endoscopic diagnosis of gastritis in daily practice and match it with the histological diagnosis. The Kyoto classification score consisted of scores in gastric atrophy, intestinal metaplasia, enlarged folds, nodularity, and diffuse redness\cite{17}. Several studies have revealed the association of the Kyoto score with *H. pylori* infection\cite{18,19} and gastric cancer risk\cite{20,21}; however, the consistency of the Kyoto score with pathological findings has not been clarified. Therefore, this study aimed to investigate the relationship between the Kyoto score and pathological findings.

**MATERIALS AND METHODS**

**Study design and subjects**

This study was approved by the institutional review board at the Institute of Medical Science, University of Tokyo on September 21, 2013 (approval No. 25-34-0921). All participants provided written informed consent.

This cohort study consisted of participants who underwent esophagogastroduodenoscopy at Toyoshima Endoscopy Clinic from December 2013 to January 2016. Esophagogastroduodenoscopies were performed either for screening, evaluation of present symptoms, or surveillance of previous esophagogastroduodenal diseases. Inclusion criteria were as follows: Patients aged ≥ 20 years without history of gastric neoplasia, surgical gastrectomy, or *H. pylori* eradication. Exclusion criteria involved a withdrawal of consent.

Demographic characteristics including age, sex, body mass index, smoking history, habitual drinking, and first-degree family history of gastric cancer were obtained\cite{22}. A score of at least 400 on the Brinkman index was defined as positive smoking history. Consumption of at least one alcoholic drink per day was defined as habitual drinking.

**Endoscopy-based Kyoto classification score**

Endoscopic Kyoto classification score for gastritis, from 0 to 8, is based on the total scores of the following five endoscopic findings: Atrophy, intestinal metaplasia, enlarged folds, nodularity, and diffuse redness. A high score represents increased risk for gastric cancer and *H. pylori* infection\cite{23}.

Pathological atrophy is defined as the loss of normal glandular tissue of the gastric mucosa. Endoscopic atrophy was classified according to the extent of mucosal atrophy, as described by Kimura *et al.*\cite{24,25}. Non-atrophy and C1 were scored as Atrophy score 0, C2 and C3 as Atrophy score 1, and O1 to O3 as Atrophy score 2.

Pathological intestinal metaplasia is defined as a phenotypic change from the normal epithelial cell of the gastric mucosa to an intestinal phenotype. Endoscopically, intestinal metaplasia typically appears as grayish-white and slightly elevated plaques surrounded by mixed patchy pink and pale areas of the mucosa, forming an irregular uneven surface. Villous appearance, whitish mucosa, and rough mucosal surface are useful indicators for endoscopic diagnosis of intestinal metaplasia\cite{26}. Intestinal metaplasia score 0 is defined as the absence of intestinal metaplasia; Intestinal metaplasia score 1 as the presence of intestinal metaplasia within the antrum; and Intestinal metaplasia score 2 as intestinal metaplasia extending into the corpus. The Intestinal metaplasia score is calculated based on the diagnosis using the white light imaging. Intestinal metaplasia diagnosis based on image-enhanced endoscopy and chromo-endoscopy is not included in the Intestinal metaplasia score.

An enlarged fold is defined as a width of ≥ 5 mm that is not flattened or is only partially flattened by stomach insufflation. The absence and presence of enlarged folds were scored as Enlarged folds score 0 and 1, respectively.

Nodular gastritis is characterized by a miliary pattern resembling “goose flesh” mainly located in the antrum. The absence and presence of nodularity was scored as Nodularity score 0 and 1, respectively.

Diffuse redness refers to uniform redness with continuous expansion observed in...
non-atrophic mucosa mainly in the corpus\cite{23}. Regular arrangement of collecting venules (RAC) is a condition where collecting venules are arranged in the corpus. From a distance, it appears like numerous dots; up close, it has the appearance of a regular pattern of starfish-like shapes. The absence of diffuse redness, presence of mild diffuse redness or diffuse redness with RAC, and severe diffuse redness or diffuse redness without RAC were scored as Diffuse redness score 0, 1, and 2, respectively.

**Pathology (topographic distribution of neutrophil activity)**

We obtained biopsy specimens from two sites, the greater curvature of the corpus and the antrum\cite{25}. One experienced gastrointestinal pathologist diagnosed neutrophil activity score based on the updated Sydney System in hematoxylin and eosin staining. Neutrophil infiltration was graded on a scale of 0-3 (none, 0; mild, 1; moderate, 2; severe, 3).

Based on the topographic distribution of neutrophil infiltration, the patients were divided into four categories: “inactive stomach,” “antrum-predominant gastritis,” “pangastritis,” and “corpus-predominant gastritis.” When neutrophil activity was null for the antrum and the corpus, the diagnosis was “inactive stomach.” When the antrum score was larger than that of the corpus, the diagnosis was “antrum-predominant gastritis.” When neutrophil activity was positive, and the antrum score was equal to that of the corpus, the diagnosis was “pangastritis.” When the corpus score was larger than that of the antrum, the diagnosis was “corpus-predominant gastritis\cite{11,26}.”

**The serum anti-\textit{H. pylori} antibody**

Patients’ blood samples were obtained on the day of esophagogastroduodenoscopy. The serum antibody titer was measured by an enzyme-linked immunosassay kit using antigens derived from Japanese individuals: E-plate Eiken \textit{H. pylori} antibody II kit (Eiken Chemical, Tokyo, Japan). We defined a cut-off value of 10 U/mL as positivity as the manufacturer recommended\cite{13-15}.

**Statistical analysis**

We tested the association between the Kyoto classification score, including Atrophy, Intestinal metaplasia, Enlarged folds, Nodularity, and Diffuse redness score, and the four categories of topographic distribution of neutrophil activity by Kruskal–Wallis and Steel–Dwass analysis. A multinomial logistic regression analysis was performed using the four categories of gastritis as objective variables. Sex, age, body mass index, drinking, smoking habit, first-degree family history of gastric cancer, serum \textit{H. pylori} antibody, and the Kyoto score were used as explanatory variables. A \( P \) value of < 0.05 was defined as statistical significance. Calculations were carried out using the statistical software Ekuseru-Toukei 2015 (Social Survey Research Information Co., Ltd., Tokyo, Japan).

**RESULTS**

A total of 327 patients (comprising 50.7\% women, with an average age of 50.2 years) were enrolled in this study. \textit{H. pylori} infection rate was 82.9\% with a mean Kyoto score of 4.63 (Table 1). The Kyoto score was associated with the topographic distribution of neutrophil activity \((P < 0.001\) calculated by Kruskal–Wallis test). Kyoto scores were significantly higher in the order of inactive stomach, antrum-predominant gastritis, pangastritis, and corpus-predominant gastritis (3.05, 4.57, 5.21, and 5.96, respectively; Figure 1). Table 2 shows that each individual score of endoscopic findings (\textit{i.e.}, atrophy, intestinal metaplasia, enlarged folds, nodularity, and diffuse redness) was correlated with the topographic distribution of neutrophil activity. On multivariate analysis, the Kyoto score, age, and serum \textit{H. pylori} antibody were independently associated with the topographic distribution of neutrophil activity (Table 3).

**DISCUSSION**

Our study revealed that the Kyoto score was associated with the topographic distribution of neutrophil activity. Uemura \textit{et al}\cite{11} reported the significance of gastritis topography, and relative risks of gastric cancer for pangastritis and corpus-

P value was calculated using Kruskal–Wallis test.

Predominant gastritis were 15.6 and 34.5, respectively, as compared with antrum-predominant gastritis. Namely, the risk of gastric cancer increased in the order of antrum-predominant gastritis, pangastritis, and corpus-predominant gastritis. In this study, Kyoto score also increased in a similar order.

Our data also showed that age, endoscopic atrophy score, and endoscopic intestinal metaplasia score increased in the order of pathologically antrum-predominant active gastritis, pangastritis, and corpus-predominant gastritis. Correa’s cascade in *H. pylori*-associated gastritis follows the following consecutive steps: (1) Normal gastric mucosa; (2) Nonatrophic antrum-predominant active gastritis; (3) Atrophy; (4) Intestinal metaplasia; (5) Dysplasia; and (6) Cancer. Atrophic gastritis progresses from the antrum to the corpus, neutrophils are mainly infiltrated in the antrum. This condition could correspond to antrum-predominant active gastritis. When atrophic gastritis progresses from the antrum to the corpus, neutrophil infiltration in antrum and corpus would be similar. This condition could correspond to pangastritis. Along with the atrophic gastritis progression, intestinal metaplasia occurs, especially in the antrum. Since intestinal metaplasia could be a harsh environment for *H. pylori*, topographic distribution of *H. pylori* could alter from the antrum to the corpus. The density of *H. pylori* was also correlated with neutrophil activity. After the emergence of antral intestinal metaplasia, neutrophil activity decreases in the antrum, and the status could be categorized as corpus-predominant gastritis. Namely, pathologically active gastritis could progress in the order of antrum-predominant gastritis, pangastritis, and corpus-predominant gastritis.

P value was calculated using the multinomial logistic regression analysis.

Figure 1 Kyoto score according to the topographic distribution of neutrophil activity. Box-plots depicting the average Kyoto score. P value was calculated using the Steel-Dwass test.

Predominant gastritis (Figure 2). Imagawa et al.\(^\text{(32)}\) also suggested that gastritis topography changes in the order of antrum-predominant gastritis, pangastritis, and corpus-predominant gastritis as age advances. In our study, endoscopic atrophy and intestinal metaplasia were associated with the development of pathologically active gastritis.

A number of studies have shown that pathological topography of neutrophil infiltration was correlated with gastric cancer risk\(^\text{(32)}\). Sakitani et al.\(^\text{(35)}\) demonstrated that neutrophil infiltration in the corpus was a risk factor for gastric cancer, especially for the diffuse-type cancer. Matsuhisa et al.\(^\text{(34)}\) showed that among H. pylori-positive patients, corpus-predominant gastritis was common in elderly Japanese and Chinese whose prevalence of gastric cancer were high, whereas antrum-predominant gastritis was prevalent in Thailand and Vietnam, which had low incidence of gastric cancer. We previously reported that corpus-predominant gastritis and pangastritis were associated with the risk allele of Prostate Stem Cell Antigen gene, a gastric cancer-related single nucleotide polymorphism. The patients with corpus-predominant gastritis and the pangastritis had low expression of Prostate Stem Cell Antigen in the gastric mucosa,
Figure 2  Representative images of four categories of gastritis. A-C: Inactive stomach. A 49-year-old woman. Kyoto score: 3; Atrophy score: 1; Intestinal metaplasia score: 0; Enlarged folds score: 0; Nodularity score: 0; Diffuse redness score: 2; D-F: Antrum-predominant gastritis. A 37-year-old man. Kyoto score: 5; Atrophy score: 1; Intestinal metaplasia score: 0; Enlarged folds score: 1; Nodularity score: 1; Diffuse redness score: 2; J-L: Corpus-predominant gastritis. A 51-year-old woman. Kyoto score: 6; Atrophy score: 2; Intestinal metaplasia score: 2; Enlarged folds score: 0; Nodularity score: 0; Diffuse redness score: 2. Greater curvature of the corpus (A, D, G and J); Lesser curvature of the corpus (B, E, H and K); Antrum (C, F, I and L).

CONCLUSION

In conclusion, the Kyoto classification score was associated with topographic distribution of neutrophil activity.
ARTICLE HIGHLIGHTS

Research background
The pathological topographic distribution of neutrophil activity in the gastric mucosa correlates to gastric cancer development. Endoscopy-based Kyoto classification of gastritis has also been reported to be associated with gastric cancer risk.

Research motivation
The consistency of the Kyoto classification score with the topographic distribution of neutrophil activity was not clear.

Research objectives
To investigate the association between endoscopic findings of gastritis based on the Kyoto classification and pathological topography of neutrophil activity.

Research methods
This study consisted of participants who underwent esophagogastroduodenoscopy at the Toyoshima Endoscopy Clinic from December 2013 to January 2016. We obtained two-points biopsy samples from the greater curvature of corpus and antrum. Based on the pathological topographic distribution of neutrophil activity, the subjects were divided into four categories: Inactive stomach, antrum-predominant gastritis, pangastritis, and corpus-predominant gastritis. We tested the association between the Kyoto classification score, including Atrophy, Intestinal metaplasia, Enlarged folds, Nodularity, and Diffuse redness score, and the four categories of topographic distribution of neutrophil activity.

Research results
We enrolled 327 patients. The Kyoto scores were significantly higher in the order of inactive stomach, antrum-predominant gastritis, pangastritis, and corpus-predominant gastritis (3.05, 4.57, 5.21, and 5.96, respectively). Especially, Atrophy score and Intestinal metaplasia score were correlated with the topographic distribution of neutrophil activity. On multivariate analysis, the Kyoto score, age, and serum Helicobacter pylori antibody were independently associated with the topographical distribution of neutrophil activity.

Research conclusions
Endoscopic findings of gastritis based on the Kyoto classification were associated with the pathological topographic distribution of neutrophil activity and showed the stepwise increase in the order of inactive stomach, antrum-predominant gastritis, pangastritis, and corpus-predominant gastritis.

Research perspectives
Our study supports the hypothesis that endoscopic findings based on the Kyoto score are useful for the assessment of gastric cancer risk. However, further studies are warranted to clarify the association between the Kyoto classification of gastritis and gastric cancer risk.
