

**A****B**

**Supplementary Figure 1** PCLS cut from normal liver tissue exhibit consistency in performance but a gradual decline in viability over time in static culture. A: XY scatter plot of typical slice weights of PCLS cut from 6 different liver specimens, with mean mean  $\pm$  SEM of cohort indicated. B: Viability of PCLS in culture using the MTT assay. MTT signal was normalized per 500 mg of tissue and data is represented as % viability compared to control at 0 hours. Data generated from  $n = 4$  normal livers samples with 27 slices in total  $\pm$  SEM. Significance represented as \*\*\* $P < 0.001$  paired  $t$  test. C: representative images of PCLS from a donor liver after 24 h in control media or media containing 250  $\mu$ mol/L Oleic acid. Original magnification 20  $\times$ .

**Supplementary Figure 2 Analysis of gene expression by quantitative qPCR analysis.** mRNA expression of indicated genes in whole liver RNA from normal, steatotic, NASH, and ALD livers using fluidigm qPCR array®, run on triplicate arrays. Results are expressed as the mean fold change in gene expression normalized to pooled endogenous controls  $\beta$ -actin and GAPDH relative to normal livers defined as 1. Data are averaged from five normal l, four steatotic, three NASH, and four ALD livers and magnitude of gene expression response is indicated by the colour scale to the left of the heatmap. Raw data can be found in Supplementary Table 3.

Fold change in gene expression in 12 replicate precision cut liver slices prepared from 2 independent human donor liver samples run on triplicate array plates. Slices were treated with 200µm methylamine for approximately 4.5 hours. RNA was extracted and mRNA expression was carried out using a fluidigm qPCR array® Results are expressed as the mean fold change in gene expression normalized to pooled endogenous controls β-actin and GAPDH relative to untreated control livers. Statistical analyses for effects of methylamine on each individual liver donor are shown and  $P < 0.05$  was considered as significantly different.

Raw data for analysis of gene expression by quantitative qPCR analysis. mRNA

expression of indicated genes in whole liver RNA from normal, steatotic, NASH, and ALD livers using fluidigm qPCR array®, run on triplicate arrays. Results are expressed as the mean fold change in gene expression normalized to pooled endogenous controls  $\beta$ -actin and GAPDH relative to normal livers defined as 1 . Data are averaged from five normal l, four steatotic, three NASH, and four ALD livers. Data are expressed as a heatmap in Supplementary Figure 2.
