n-3 fatty acids given preoperatively for five days of on the inflammatory and immunologic markers 63 and also on the clinical outcome in patients undergoing liver resection. Thirty-two patients undergoing liver resection were included. They study suggests that there is no benefit of preoperative immunonutrition in well-nourished patients undergoing elective liver resection. Immunonutrition did not result in suppression of postoperative inflammation compared to standard care. The study is a well-designed and well-written one and can be accepted for publication.

SPECIFIC COMMENTS TO AUTHORS

The study was well designed and properly done, but failed to show any findings for decrease of postoperative inflammation or complications. It may be not worth of immunonutritional intervention for well-nourished patients. As the author mentioned in

discussion, study for malnourished patients of major hepatectomy are necessary. I have one question and one comment. Were there any differences between two groups in general nutritional indicators such as triglyceride and total cholesterol before nutritional intervention? I wonder whether the IMN group was over stressed on the contrary because of hypercalory.
