**Basic Study**

ENTPD1-AS1-miR-144-3p mediated high expression of COL5A2 correlates with poor prognosis and macrophage infiltration in gastric cancer

COL5A2 gastric cancer

Hanmei Yuan, Xiaofeng Pu, Hui Wu, Chao Wu
Abstract

BACKGROUND
Gastric cancer (GC) is a malignant tumor with high morbidity and mortality. Expression of COL5A2 is significantly elevated in GC. Abnormal expression of ncRNAs has been found in GC, including miRNA and IncRNA. Competing endogenous RNA (ceRNA) network plays an important regulatory role in GC. However, its specific regulatory mechanism has not been elucidated.

AIM
To gain insight into the ncRNA regulatory mechanism and immune microenvironment related to COL5A2 in GC.

METHODS
RNA sequencing data and clinical information from The Cancer Genome Atlas (TCGA) data portal were used to analyze the expressions of COL5A2, miRNA and IncRNA related to the prognosis of GC. Cox regression analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis were performed to assess the risk factors and relevant function of COL5A2. StarBase was used to predict the interaction of miRNA-IncRNA or miRNA-mRNA in GC. The relationship between COL5A2, miR-144-3p and ENTPD1-AS1 was verified by dual luciferase reporter assay. The association of COL5A2 with immune cell infiltration was analyzed using the Tumor Immune Estimation Resource (TIMER) database and single sample gene set enrichment analysis. The expression of COL5A2 and macrophages in paired GC tissues were detected by immunohistochemical staining.

RESULTS
We verified that the upregulation of COL5A2 expression was associated with the prognosis of GC and was an independent risk factor for GC. miR-144-3p was downregulated and correlated with the prognosis of GC. miR-144-3p regulated the
expression of COL5A2 through direct interaction with miR-144-3p. ENTPD1-AS1 was elevated in GC and competitively bound to miR-144-3p, thus inhibiting the expression of miR-144-3p. ENTPD1-AS1 enhanced the expression of COL5A2 through sponging miR-144-3p. Compared to paired normal tissue, COL5A2 expression was upregulated at the protein level, especially in the middle and late stages of GC. The high expression of COL5A2 was positively linked to macrophage infiltration in GC.

CONCLUSION

COL5A2 regulated by ENTPD1-AS1-miR-144-3p is associated with poor prognosis and macrophage infiltration in GC. This could be a new biomarker and therapeutic target in GC.

**Key Words:** COL5A2; ncRNAs; Macrophage infiltration; Prognosis; Gastric cancer

Yuan H, Pu X, Wu H, Wu C. ENTPD1-AS1-miR-144-3p mediated high expression of COL5A2 correlates with poor prognosis and macrophage infiltration in gastric cancer. *World J Gastrointest Oncol* 2023; In press

**Core Tip:** Gastric cancer(GC) is a malignant tumor with high fatality rate. ceRNA network and infiltration of immune cells play an important role in the development of GC. In this study, we verified that high expression of COL5A2 was closely related to poor prognosis and was an independent risk factor for GC. We predicted and validated that IncRNA ENTPD1-AS1 regulated the expression of COL5A2 through sponging miR-144-3p. Additionally, we confirmed that upregulation of COL5A2 expression strongly correlated with immune infiltration of macrophages. ENTPD1-AS1-miR-144-3p-COL5A2 might be a new therapeutic target for GC.

**INTRODUCTION**
Gastric cancer (GC) remains the fourth leading cause of cancer death worldwide. About 95% of cases are gastric adenocarcinoma (GAD) subtype\[1\]. The survival rate of GC has improved with medical advances. However, the median survival time for advanced GC is < 12 mo\[2\]. Accordingly, exploring the molecular mechanism of gastric cancer is of great significance for finding better therapeutic targets and better treatment.

The extracellular matrix is mainly composed of collagen and is related to proliferation, differentiation, migration, and metabolism of cancer\[3\]. Recent studies have shown that Collagen type V α2 (COL5A2), one of the collagen genes, is upregulated in several types of cancer and associated with immune cells infiltration\[4, 5\]. Traditionally, COL5A2 is considered tightly related to the occurrence of classical Ehlers-Danlos syndrome \[6, 7\]. However, high expression of COL5A2 is found to be associated with worse prognosis and drug resistance\[8-10\]. COL5A is also found closely associated with immune cell infiltration, which may be related to the inhibitory effect of collagen on the production of CCL2\[5\]. In proliferative diabetic retinopathy, COL5A2 is closely related to the infiltration of M2 macrophages\[11\].

Noncoding RNAs (ncRNAs), such as microRNAs (miRNAs), long noncoding RNAs (lncRNAs) and circular RNAs (circRNAs), are critically involved in GC development\[12\]. ncRNAs could affect the proliferation, invasion, migration and metastasis of GC by regulating target miRNA genes\[13\]. Studies have revealed that MiR-144-3p can affect the occurrence, development, and prognosis of cancer by inhibiting the expression of target genes\[14, 15\]. ncRNA can upregulate the expression of cancer-promoting genes by inhibiting the expression of miRNA-144-3p\[16, 17\]. ENTPD1-AS1 is an antisense lncRNA that may be associated with short stature\[18\]. Recently, ENTPD1-AS1 is considered to be a new ncRNA that regulates the proliferation and apoptosis of cancer cells and also serves as a prognostic marker in glioblastoma multiforme\[19, 20\]. However, the ncRNA regulatory mechanism and immune infiltration of COL5A2 are still unclear in GC.

In this study, we verified that high expression of COL5A2 in GC was closely related to poor prognosis and was an independent risk factor. We predicted and verified a new
upstream regulatory ceRNA network, namely, ENTPD1-AS1 regulated COL5A2 expression through sponging miR-144-3p. We confirmed that upregulation of COL5A2 expression strongly correlated with immune infiltration of macrophages. ENTPD1-AS1–miR-144-3p regulation of COL5A2 correlated with poor prognosis and macrophage infiltration in GC.

MATERIALS AND METHODS

Sample collection
We collected 40 paired GC and normal specimens from the Eighth Affiliated Hospital of Sun Yat-Sen University. These tissues were obtained from the patients undergoing GC surgery. All the patients signed informed consent forms. This research was approved by the Ethics Committee of the Eighth Affiliated Hospital of the Sun Yat-Sen University.

Cell culture
Human Embryonic Kidney cells (293T) and human gastric adenocarcinoma cell line (AGS) were cultured in dulbecco's modified eagle medium (DMEM) (GIBCO, Invitrogen, Carlsbad, CA, USA) containing 10% FBS (GIBCO) and 100 U/mL penicillin, and 0.1 mg/mL streptomycin (Invitrogen, Carlsbad, CA, USA).

Expression and prognostic analysis of COL5A2 in gastric cancer
The Gene Expression Profiling Interactive Analysis (GEPIA; http://gepia.cancer-pku.cn/) database was utilized for the expression and prognostic analysis of COL5A2 in numerous cancers.

Clinical information and data acquisition of patients with GAD
The mRNA expression data of GAD in tumor and normal tissues (446 cases of tumor, and 45 cases of normal tissue) and clinical material were obtained from TCGA public database (https://portal. gdc. cancer. gov). The basic information of human miRNA was downloaded from http://www.mirbase.org. We conducted a differential analysis and survival analysis on the expression of COL5A2 in normal tissues and gastric cancer
tissues. Data transformation was achieved using Perl script. R version 4.1.2 was used in several analyses.

**Cox regression analysis**
We organized the clinical data of GAD and matched the expression of COL5A2 in the corresponding samples. Samples with incomplete or missing data were excluded from this analysis, and finally 322 specimens were obtained. Univariate and multivariate Cox proportional hazards regression models were used to assess COL5A2 for prediction of overall survival (OS).

**Functional enrichment analysis of COL5A2**
We analyzed Kyoto Encyclopedia of Genes and Genomes (KEGG) signaling pathway enrichment of COL5A2 by gene set enrichment analysis (GSEA). We found gene markers corresponding to 22 immune cells and extracted the expression of these gene markers from the TCGA data. Using single sample GSEA (ssGSEA), we determined the infiltration of these immune cells in COL5A2 high expression and low expression groups.

**Prediction and analysis of the interaction between mRNA and miRNA or miRNA and IncRNA**
We used starBase (http://starbase.sysu.edu.cn/) to predict the interaction of miRNA-mRNA or miRNA-IncRNA interaction. StarBase is a powerful target gene prediction software, and it includes 7 functional domains for prediction. We set the screening conditions for at least two sites that considered the gene to be the target gene of COL5A2, and the gene was retained. The expression data of miRNA-144-3p and ENTPD1-AS1 are from the TCGA database. We conducted the expression analysis, correlation analysis, and survival analysis using R version 4.1.2.

**Dual-luciferase reporter assay**
The sequences of COL5A2 or ENTPD1-AS1 that may bind to miRNA-144-3p were cloned into the pmiGLO vector (Sangon Biotech Co., Ltd. Shanghai, China). We constructed four kinds of double luciferase report plasmids: COL5A2 3'UTR-wt, COL5A2 3'UTR-mut, ENTPD1-AS1-wt and ENTPD1-AS1-mut.

**SiRNAs and miRNA mimics**

siRNAs, miRNA mimics and their corresponding negative controls (NC) were designed by GenePharma Co., Ltd., (Shanghai, China). The sequence is as follows: MiR-144-3p mimics: (UACAGUAUAAGAUGAUGUACU), mimics NC: (UUGUACUACACAAAGUACUG), si-ENTPD1-AS1: (GGCCCGUAAUGGAGAUCGATT, UCGAUCUCCAUUACGGGCCTT), si-NC: (UUCUCGGAACGUGUCACGUTT, ACGUGACACGUUCGGAGAATT).

**Cell transfection**

We seeded cells into 24-well plates at a density of 1.5x10^6 cells per well. When the cells reached 60% to 70%, dual luciferase reporter vector and miR-144-3p mimics or negative control (NC) mimics were transfection into 293T cells and AGS cells, in the presence of Lipofectamine™ and P3000™ (L3000001, Invitrogen, USA). In some experiments, mixture of Lipofectamine™ and miR-144-3p or si-ENTPD1-AS1 was transfection into AGS cells. After 6 h, fresh medium was replaced. 48h later, Fluorescence intensity is detected by Dual-Luciferase® Reporter Assay System ((E1910, Promega, USA).

**qRT-PCR**

RNAs were extracted by Trizol from AGS cells. RNA was reversely transcribed into cDNA with Evo M-MLV RT Premix (AG11701, Accurate Biotechnology, Hunan, China.) and then detected gene expression with SYBR® Green Premix Pro Taq HS qPCR Kit for qPCR (AG1170, Accurate Biotechnology, Hunan, China). The primers were synthesized by Sangon Biotech Co., Ltd (Shanghai, China). COL5A2: (Forward: GGATCACAGGGACCAAGAGGAG, Reverse:
GCACCAGGTGACCAGGAACAC, ENTPD1-AS1 (Forward: CCTGCCTCTGCCTCCAAAGTAG, Reverse: TCCGAGACCAGCCTGACCAAC), hsa-
miR-144-3p (RT Primer: GTCGTATCCAGTGCAGGGTGACAGGTATTCGCACTTGATACGCAGCATAC, Forward: GCCGCAGTGATAGTAGATA, Reverse: ATCCAGTGCAGGGTGCCAGGG). U6 (Forward: GGAACGATACAGAGAGATCG, Reverse: TGGAAACGCTTCACGAATTTTGC), GAPDH (Forward: TGTGTCGTGCAGATCTTAAGA Reverse: GCAGCTGTGACACACAGTA). miRNA was detected by stem-loop. U6 or GAPDH as internal control. The relative expression of genes is calculated by 2-ΔΔCt.

**Correlation Analysis of COL5A2 and Immunological Checkpoints**

Tumor IMmune Estimation Resource (TIMER) database (https://cistrome.shinyapps.io/timer/) integrated the results of multiple algorithms based on the sequencing results of TCGA. We used the TIMER database and GEPIA to analyze the correlation between COL5A2 and immune cells or immune checkpoints.

**Immunohistochemistry**

All tissue slides were dewaxed, hydrated, and antigen was retrieved. We inactivated endogenous enzymatic activity and blocked nonspecific sites. Primary and secondary antibodies were incubated and rendered with Diaminobenzidine (DAB). The concentration of primary antibodies was anti-COL5A2 (1:100, Thermo Fisher, PA5-38880, USA), anti-CD68 (1:2000, Abcam, ab955, UK). We selected the corresponding secondary antibody according to the primary antibody (1:100, Santa Cruz Biotechnology, sc-2357/sc-516102; DAB detection kit (50:1, Servicebio, G1212, China). All slides were observed and counted by a Carl Zeiss microscope (Axio Imager A2, Germany). The CD68+ cell counts were conducted by taking the average value of three high power fields (HP). Based on the number of CD68+ cells, the macrophage infiltration was categorized into weak (30–60/HP), moderate (60–90/HP), and strong (>90/HP) subgroups.
Statistical analysis
R with the survminer, survival, Ggforest and limma packages was used for analysis. GraphPad 8 with unpaired t-test and Spearman correlations were used for some analyses. P < 0.05 was considered statistically significant.

RESULTS
Expression and prognostic analysis of COL5A2 in pan-cancer
To identify the differential expression of COL5A2 in pan-cancer, the expression of COL5A2 was assessed in 18 types of cancer by GEPIA. The expression of COL5A2 was significantly increased in nine cancers compared with the normal group (Figure 1A–1I, p<0.05). There was no significant difference in the other nine cancers (Supplementary Figure 1). Among the cancers with significant differences in COL5A2 expression, OS analysis was conducted using GEPIA database. Only in GC was higher expression of COL5A2 related to worse prognosis (Figure 1Q, P = 0.01). No significant prognostic difference in other cancers was observed (Figure 1J–1R).

Cox regression analysis and KEGG enrichment analysis of COL5A2 in GC
To verify the results obtained from the GEPIA database, we analyzed the expression and survival prognosis of COL5A2 using RNA-sequencing data from TCGA. In line with previous studies\textsuperscript{[21]}, significantly high expression of COL5A2 was found in TCGA data and 27 paired specimens (Figures 2A and 2B). We performed survival analysis and found a significant difference in OS between high and low COL5A2 expression groups (Figure 2C, P = 0.018).

Excluding patients with missing or incomplete information, 322 of the 433 patients were included in the cox regression analysis. From clinical information, it can be seen that patients with gastric cancer are mainly in the middle and late stages, with a high rate of lymph node metastasis, less distant metastasis, and a high mortality rate (Supplementary Table 1). Cancer stage, especially N stage, was the most important
prognostic indicator. Age, T stage, and COL5A2 expression were risk factors for GC (Table 1). To determine whether these risk factors were independent of other factors as independent prognostic factors, multivariate Cox regression was conducted. Only age [1.03(1.01-1.1), \( P = 0.002 \)] and expression of COL5A2 [1.23(1.05-1.5), \( P = 0.013 \)] were independent prognostic factors (Figure 2D).

Dividing GCs into COL5A2 high- and low-expression groups, we used KEGG enrichment to analyze which signaling pathways were associated with differential genes between the two groups. According to Normalized enrichment score (NES), nominal \( P \) value, the 10 most enriched signaling pathways in KEGG are shown in Supplementary Table 2). To be more concise, we integrated these signaling pathways into one diagram (Figure 2E). The most significantly enriched signaling pathways in the COL5A2 high expression group were the interaction between extracellular matrix and receptors, focal adhesion, and some classic cancer-related signaling pathways such as the transforming growth factor-\( \beta \) signaling pathway.

**miRNAs that interact with COL5A2 in GC**

To investigate whether COL5A2 was regulated by miRNAs in GC, we used starBase to predict which miRNAs would bind to COL5A2. There were 69 miRNAs with the potential to bind to COL5A2, and it was visualized by cytoscape (Supplementary Figure 2). According to the principle of gene regulation, miRNA should negatively correlate with COL5A2. Thus, we set the screening condition that miRNA was negatively correlated with COL5A2 and \( P < 0.001 \). For COL5A2, there was upregulation in GC, so the target miRNA downregulation in GC compared with normal tissues. miR-29c-3p (R= -0.27, \( P = 2.1e-07 \)) and miR-144-3p (R= -0.16, \( P = 0.0017 \)) were negatively correlated with COL5A2 and markedly downregulated in GC (Figures 3A, 3B (\( P = 1.4e-09 \)), 3D and 3E (\( P = 0.013 \)). We analyzed the prognostic impact of miR-29c-3p and miR-144-3p. Only low expression of miR-144-3p had a significant effect on survival (Figures 3C (\( P = 0.058 \)) and 3F (\( P = 0.041 \)). All these findings meant that miR-144-3p is the most likely upstream miRNA to regulate COL5A2 in GC.
**Prediction and analysis of upstream lncRNAs of miR-144-3p**

lncRNAs can competitively bind to miRNAs, which leads to upregulation of oncogenes. We predicted using starBase which lncRNAs would interact with miR-144-3p. We examined the correlation between lncRNAs, COL5A2 and miR-144-3p (Table 2). For downregulated miR-144-3p, expression of lncRNAs should be upregulated in GC. Among all lncRNAs, ENTPD1-AS1(R=−0.32, P = 1.6e-10), NORAD (R=−0.21, P = 3e-05), and ZNF460-AS1(R=−0.24, P = 2.1e-6) were negatively correlated with miR-144-3p (Figures 4A, 4E and 4I). ENTPD1-AS1(r = 0.11, P = 0.036) and NORAD (r = 0.14, P = 0.0067) were positively correlated with COL5A2. ZNF460-AS1(R=−0.042, P = 0.42) had a negative correlation with COL5A2 (Figures 4B, 4F and 4J). We analyzed the expression of lncRNA in GC, and three lncRNAs were significantly upregulated in GC (Figures 4C(P = 3.6e-06), 4G(P = 1e-10) and 4K(P = 0.011)). Kaplan–Meier analysis revealed that the higher the ENTPD1-AS1 expression, the better the OS (Figures 4D(P = 0.002), 4H(P = 0.229) and 4L(P = 0.351). By taking into account expression and prognostic analysis, our data suggest that ENTPD1-AS1 is the most likely lncRNA to regulate the miR-144-3p/COL5A2 axis in GC.

**lncRNA ENTPD1-AS1 enhances the expression of COL5A2 through sponging miR-144-3p**

In order to verify the interaction of ENTPD1-AS1, miR-144-3p and COL5A2, we constructed dual luciferase reporter vector (Figures 5A). The results showed that in the presence of miR-144-3p mimics, the luciferase activity of COL5A2 3’UTR-wt group was significantly reduced compared to COL5A2 3’UTR-mut group in both 293T cells and AGS cells. However, when transfected with negative control(NC) mimics, there was no difference in fluorescence intensity between COL5A2 3’UTR-wt group and COL5A2 3’UTR-mut group (Figures 5B and 5C). Similarly, the luciferase activity was reduced when miR-144-3p mimics interacted with ENTPD1-AS1-wt instead of ENTPD1-AS1-mut (Figures 5D and 5E). Additionally, when miR-144-3p enrichment was present, the
expression of COL5A2 was decreased in AGS cells. When transfected with NC mimics, the change of fluorescence intensity disappeared (Figures 5F and 5G). Compared to si-NC, si-ENTPD1-AS1 led to a decrease of miR-144-3p (Figures 5H and 5I). All these results suggested that ENTPD1-AS1 might promote the expression of COL5A2 by suppressing the expression of miR-144-3p.

**COL5A2 has a correlation with immune checkpoints in GC**

For immunotherapy having a low response in many cancers, there is a pressing need to find new target genes that could improve the efficacy of immunotherapy. Considering the cancer-promoting role of COL5A2, we analyzed the association of COL5A2 with checkpoints using the TIMER database. Our analyses revealed a high correlation between COL5A2 and CD274 and a lower correlation between COL5A2 and CTLA4 or PDCD1 (Figure 6A). We observed similar results in the GEPIA database (Figures 6B–6D). These results suggest that COL5A2 mediates immune escape in GC.

**COL5A2 is associated with immune cell infiltration in GC**

To explore the link between COL5A2 and immune cells, we determined the relationship between COL5A2 and immune cell biomarkers. We found a significant and positive association with COL5A2 and M2 macrophage biomarkers (CD163, VSIG4 and MS4A4A). The other immune cells biomarkers had a lower correlation or only some of the markers had a correlation with COL5A2 (Table 3). The TIMER database indicated that COL5A2 was significantly associated with infiltration of various immune cells, including neutrophils, macrophages and dendritic cells, but most correlated with macrophage infiltration (Figure 7A). We used ssGSEA to analyze the enrichment of 22 types of immune cells in groups with high and low COL5A2 expression. We discovered a significant difference in immune infiltration of macrophages, neutrophils and B memory cells between COL5A2 high and low expression groups. In line with our previous results, macrophage infiltration was most correlated with COL5A2 (Figure 7B, p<0.001). COL5A2 is significantly positively linked to macrophage infiltration.
Expression of COL5A2 and its correlation with macrophages in GC

To verify the correlation between COL5A2 and macrophage infiltration in GC, we detected expression of COL5A2 and macrophages (CD68+) by immunohistochemistry in GC and paired normal tissues. According to the stain density, we divided the expression of COL5A2 into three levels, including weak, moderate, and strong staining, with corresponding scores of 1–3. According to the number of CD68+ cells, we divided macrophage infiltration into three groups: weak (30–60/HP), moderate (60–90/HP), and strong (> 90/HP) (Figure 8A). The expression of COL5A2 at the protein level was clearly higher than in the paired peritumor tissues (Figure 8B, P = 0.025). Expression of COL5A2 between low stage GC (I and II) and high stage GC (III and IV) was assessed to determine whether COL5A2 was related to GC stage. Compared with low stage GC, the level of COL5A2 was significantly higher in high stage GC (Figure 8C, P = 0.0106). Pearson correlation analysis was performed to determine the relation between COL5A2 expression and macrophage infiltration in GC. Clearly, macrophage infiltration was consistent with COL5A2 staining intensity (Figure 8D, r = 0.7459, p<0.0001). These results demonstrated that high expression of COL5A2 was observed in GC and COL5A2 was strongly positively correlated with macrophage infiltration.

DISCUSSION

GC is one of the tumors with high morbidity and mortality. Collagen is upregulated in advanced GC, and some collagen genes can be used as cancer biomarkers and can distinguish precancerous from cancerous lesions[22, 23]. Several studies have shown that COL5A2 is upregulated in various cancers and can be used as a prognostic marker [24, 25]. Here, we explored the upstream regulatory molecular mechanisms and immune function of COL5A2 in GC. We confirmed that COL5A2 was enriched and can predict poor prognosis in GC. We verified that COL5A2 is closely related to macrophage infiltration in GC. A new ceRNA network, ENTPD1-AS1-miR-144-3p–COL5A2 was
identified, which may partially explain the upstream regulatory mechanism of COL5A2 in GC.

We confirmed that COL5A2 was increased in a number of tumors, but it was associated with worse survival only in GC. Cox regression analysis found that COL5A2 could be an independent prognostic factor for GC. KEGG enrichment analysis found that high expression of COL5A2 was associated with multiple signal transduction pathways. All these results revealed that COL5A2 was strongly associated with worse prognosis and has a crucial role in the development of GC. ceRNA plays a critical role in the regulation of gene expression in GC [26, 27]. The mechanism of ceRNA mainly refers to that IncRNAs inhibit the negative regulation of miRNAs. For example, upregulation of circular RNA KIF4A expression in GC can regulate the miRNA-144-3p–EZH2 axis to facilitate cell migration and invasion[28]. To investigate whether COL5A2 was regulated by the ceRNA network, we predicted by starBase which miRNAs could bind to COL5A2. We discovered that miR-29c-3p and miR-144-3p were most likely to regulate COL5A2 in GC. Although miR-29c was reduced in GC and associated with tumor aggressiveness, our findings suggest that miR-29c-3p plays a role in GC by regulating COL5A2. Some studies have demonstrated that miR-144-3p inhibited cancer proliferation and migration, potentially serving as a biomarker in GC [16, 29], which is consistent with our results that miR-144-3p was downregulated and closely related to prognosis in GC. Considering correlation analysis and expression analysis, ENTPD1-AS1, NORAD, and ZNF460-AS1 might regulate COL5A2 through a ceRNA network in GC. Three IncRNAs were negatively correlated with miR-144-3p, but only ENTPD1-AS1 and NORAD were positively correlated with COL5A2. Therefore, we focused on ENTPD1-AS1 and NORAD. Survival analysis suggested that ENTPD1-AS1 was significantly associated with GC survival. The most potentially upregulated IncRNAs were ENTPD1-AS1. Many IncRNAs have been identified as ceRNAs in GC, such as HOTAIR, MALAT1, NORAD and H19[30]. Some studies reported that IncRNA NORAD promoted GC cell growth by inhibiting expression of miR-608 or miR-433-3p [31, 32]. Here, we revealed that NORAD promoted the development of GC by inhibiting
expression of miR-144-3p. ENTPD1-AS1 is an antisense transcription IncRNA, which can be used as a prognostic marker in glioblastoma multiforme [19]. We confirmed that the most probable ceRNA regulatory network for COL5A2 in GC is NTPD1-AS1-miR-144-3p-COL5A2 through dual luciferase assay.

Recent studies have shown that fibrillar collagen can facilitate immune cell infiltration with bioinformatics analysis [33]. Genes associated with M2 infiltration of GC have been described in some previous studies, including COL1A1, COL4A1, COL12A1 and PDGFRB [34,35]. Wei et al. [36] identified that stromal-relevant gene clusters could be used as prognostic genes and are associated with macrophage infiltration in GC. However, most of the results were obtained through database analysis and lacked experimental validation. Similar to previous studies, we found that COL5A2 was markedly positively associated with macrophage infiltration, using the TIMER database and ssGSEA. We confirmed by immunohistochemical staining that COL5A2 was significantly highly expressed, especially in the high stage of GC and was significantly positively correlated with macrophage infiltration at the protein level by IHC staining. These results give us a more complete view that macrophage infiltration may partially explain the carcinogenesis mediated by COL5A2 in GC.

There are some limitations to this study. First, although we proved the direct interaction of miR-144-3p and COL5A2 or miR-144-3p and ENTPD1-AS1 by Dual-Luciferase Reporter Assay and siRNA transfection, further experimental verification and confirmation are needed, such as RNA Binding Protein Immunoprecipitation (RIP) and in vivo experiments. Second, COL5A2 was found to be associated with poor prognosis of GC and macrophage infiltration by in vitro experiments, the sample size was small, these results thus should be verified in COL5A2 knockout mice, and tested in big samples.

CONCLUSION
We have verified that COL5A2 is an independent risk factor and can be used as a biomarker for GC. Our results demonstrate that COL5A2 exerts a tumor-promoting effect by promoting immune cell infiltration, especially macrophage infiltration. We have identified a novel ceRNA network that facilitates COL5A2 expression in GC, namely, IncRNA ENTPD1-AS1 upregulates the expression of COL5A2 by inhibiting the expression of miR-144-3p. These results partly explained the upstream regulatory mechanism and immune mechanism of COL5A2 in GC. COL5A2-miR-144-3p-ENTPD1-AS1 has the potential to be a novel therapeutic target for GC.

**ARTICLE HIGHLIGHTS**

**Research background**

Gastric cancer (GC) is a malignant tumor with high morbidity and mortality. Expression of COL5A2 is significantly elevated in GC. However, its specific regulatory mechanism has not been elucidated.

**Research motivation**

Abnormal expression of ncRNAs has been found in GC, including miRNA and IncRNA. The ncRNA regulatory mechanism and immune microenvironment related to COL5A2 in GC are not well understand.

**Research objectives**

To explore the ceRNA regulatory mechanism and immune mechanism of COL5A2 in gastric cancer.

**Research methods**

StarBase was used to predict the interaction of miRNA–IncRNA or miRNA–mRNA in GC. The direct interaction between COL5A2, miR-144-3p and ENTPD1-AS1 was verified by dual luciferase reporter assay. The correlation between of COL5A2 and
macrophages was analyzed through bioinformatics and validated in paired GC tissues by immunohistochemical staining.

Research results
miR-144-3p interacted directly with COL5A2 and negatively regulated the expression of COL5A2. ENTPD1-AS1 was elevated in GC and competitively bound to miR-144-3p, thus inhibiting the expression of miR-144-3p. Compared to paired normal tissue, COL5A2 expression was upregulated at the protein level, especially in the middle and late stages of GC. The high expression of COL5A2 was positively linked to macrophage infiltration in GC.

Research conclusions
COL5A2 regulated by ENTPD1-AS1-miR-144-3p is associated with poor prognosis and macrophage infiltration in GC.

Research perspectives
ENTPD1-AS1-miR-144-3p-COL5A2 might be a new therapeutic target for GC.
