ABOUT COVER
Editorial Board Member of World Journal of Stem Cells, Yu-Hong Li, PhD, Associate Professor, Department of Cell Biology, Army Medical University, Chongqing 400038, China. liyuhongtmmu@hotmail.com

AIMS AND SCOPE
The primary aim of World Journal of Stem Cells (WJSC, World J Stem Cells) is to provide scholars and readers from various fields of stem cells with a platform to publish high-quality basic and clinical research articles and communicate their research findings online. WJSC publishes articles reporting research results obtained in the field of stem cell biology and regenerative medicine, related to the wide range of stem cells including embryonic stem cells, germline stem cells, tissue-specific stem cells, adult stem cells, mesenchymal stromal cells, induced pluripotent stem cells, embryonal carcinoma stem cells, hemangioblasts, lymphoid progenitor cells, etc.

INDEXING/ABSTRACTING
The WJSC is now abstracted and indexed in Science Citation Index Expanded (SCIE, also known as SciSearch®), Journal Citation Reports/Science Edition, PubMed, PubMed Central, Scopus, Biological Abstracts, BIOSIS Previews, Reference Citation Analysis, China Science and Technology Journal Database, and Superstar Journals Database. The 2023 Edition of Journal Citation Reports® cites the 2022 impact factor (IF) for WJSC as 4.1; IF without journal self cites: 3.9; 5-year IF: 4.5; Journal Citation Indicator: 0.53; Ranking: 15 among 29 journals in cell and tissue engineering; Quartile category: Q3; Ranking: 99 among 191 journals in cell biology; and Quartile category: Q3. The WJSC’s CiteScore for 2022 is 8.0 and Scopus CiteScore rank 2022: Histology is 9/57; Genetics is 68/325; Genetics (clinical) is 19/90; Molecular Biology is 119/380; Cell Biology is 95/274.

Abstract

BACKGROUND
Mesenchymal stem cells (MSCs) modulated by various exogenous signals have been applied extensively in regenerative medicine research. Notably, nanosecond pulsed electric fields (nsPEFs), characterized by short duration and high strength, significantly influence cell phenotypes and regulate MSCs differentiation via multiple pathways. Consequently, we used transcriptomics to study changes in messenger RNA (mRNA), long noncoding RNA (lncRNA), microRNA (miRNA), and circular RNA expression during nsPEFs application.

AIM
To explore gene expression profiles and potential transcriptional regulatory mechanisms in MSCs pretreated with nsPEFs.

METHODS
The impact of nsPEFs on the MSCs transcriptome was investigated through whole
Evaluation of genetic response of mesenchymal stem cells (MSCs) to nanosecond pulsed electric fields (nsPEFs)

Lin JJ, Ning T, Jia SC, Li KJ, Huang YC, Liu Q, Lin JH, Zhang XT. Genetic response of MSCs to nsPEFs

RESULTS
In total, 263 DEGs were discovered, with 92 upregulated and 171 downregulated. DEGs were predominantly enriched in epithelial cell proliferation, osteoblast differentiation, mesenchymal cell differentiation, nuclear division, and wound healing. Regarding cellular components, DEGs are primarily involved in condensed chromosome, chromosomal region, actin cytoskeleton, and kinetochore. From aspect of molecular functions, DEGs are mainly involved in glycosaminoglycan binding, integrin binding, nuclear steroid receptor activity, cytoskeletal motor activity, and steroid binding. Quantitative real-time polymerase chain reaction confirmed targeted transcript regulation.

CONCLUSION
Our systematic investigation of the wide-ranging transcriptional pattern modulated by nsPEFs revealed the differential expression of 263 mRNAs, 2 miRNAs, and 65 lncRNAs. Our study demonstrates that nsPEFs may affect stem cells through several signaling pathways, which are involved in vesicular transport, calcium ion transport, cytoskeleton, and cell differentiation.

Key Words: Nanosecond pulsed electric fields; Whole transcriptome sequencing; Mesenchymal stem cells; Genetic response; Stem cell engineering

INTRODUCTION
Mesenchymal stem cells (MSCs), as seed cells in regenerative repair, have been extensively applied in preclinical and clinical research in regenerative medicine, such as osteoarthritis[1], cartilage defects[2], and bone defects[3]. The differentiation and function of MSCs can be modulated by various exogenous signals, including biological factors[4], drug formulations[5], and physical signals[6]. The quest for an appropriate exogenous signal to regulate the functions and differentiation of stem cells remains a dynamic area of investigation for numerous researchers.

Pulsed electric fields (PEFs), as a crucial biophysical signal, can induce changes in cell membranes and alterations in intracellular calcium ion concentrations. Under specific conditions, PEFs can significantly influence cell phenotypes and regulate stem cell differentiation through multiple pathways[7,8]. However, the biological effects of traditional PEFs are relatively weak, and the time required for the emergence of a differentiating response can often range from hours to days[9]. This may be attributed to the fact that the pulse width of traditional PEFs is in the microsecond range or higher, exceeding the intrinsic charging and discharging time of cell membranes (in the range of hundreds of nanoseconds). As a result, traditional PEFs face difficulties in deeply penetrating the cell interior due to the shielding effect of the cell membrane[10]. In contrast, nanosecond PEFs (nsPEFs) represent nanosecond-duration, high-strength electric fields, with a shorter pulse width than the charging and discharging time of the cell membrane. Furthermore, nsPEFs can deeply penetrate into cellular organelles and exhibit significant biological effects[11]. In our previous research, it was found that nsPEFs can influence the osteogenic, adipogenic, and chondrogenic differentiation of MSCs by regulating DNA methylation and the MAPK signaling pathway[12]. Although nsPEFs show strong regulatory effects on MSCs differentiation, previous studies have mainly focused on specific molecules or pathways, and a comprehensive exploration of the
mechanisms by which nsPEFs regulate MSCs has not been conducted.

Transcriptomics analysis, by examining messenger RNA (mRNA), long noncoding RNA (lncRNA), microRNA (miRNA), and circular RNA (circRNA), allows for a comprehensive understanding of changes in gene expression. It also holds significant importance in unraveling alterations in biological processes. In this study, we first utilized high-throughput transcriptomics sequencing to detect the changes of mRNA, miRNA, IncRNA, and circRNA expression in MSCs after nsPEFs treatment. Additionally, we carried out Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) analyses to explore the biological processes and signaling pathways associated with differentially expressed target genes. Furthermore, we validated their expression levels using quantitative real-time polymerase chain reaction, providing further support for the application of nsPEFs in MSCs.

MATERIALS AND METHODS

Cell isolation and culture
All animal experiments were approved by the Institutional Animal Care and Use Committee of Peking University (COE-GZ-7). Rat bone marrow MSCs (rMSCs) were harvested from 8-wk-old Sprague-Dawley rats according to our previous study[13]. MSCs were cultured in expansion medium composed of Dulbecco’s modified Eagle’s medium (DMEM, Hyclone) supplemented with 10% (v/v) fetal bovine serum (Gibco) and 1% penicillin/streptomycin (Amresco), in a humidified incubator at 37 °C with 5% CO₂. Cells were trypsinized with 0.25% (w/v) trypsin (Invitrogen, Carlsbad, CA, United States) upon reaching 85% confluence. MSCs at passage 5 were used for subsequent experiments.

Application of nsPEFs
We previously found that nsPEFs (100 ns, 10 kV/cm, 1 Hz, 5 pulses) can improve the stemness of porcine bone marrow MSCs, human bone marrow MSCs, and rMSCs, and promote osteochondral defect repair in rats[12-14]. In this study, nsPEFs with the same parameters were applied to regulate MSCs performance. According to our previous study[12-14], one million MSCs were suspended in 1 mL of DMEM within a 0.4-cm gap cuvette (Bio-Rad, 165-2088, United States) and stimulated by 5 pulses of nsPEFs (100 ns at 10 kV/cm, 1 Hz), and the time interval between two pulses was 1 s. The cells were then subjected to nsPEFs with a duration of 100 ns, as previously described. Five pulses were applied at 1-s intervals between each pulse. MSCs without nsPEFs stimulation served as the control group.

RNA isolation
Total RNA was isolated from the cells 24 h after exposure with the miRNA extraction kit (Cat#TR205-200, Tanmo). Qualified total RNA was further purified with the RNAClean XP Kit (Cat#A63987, Beckman Coulter, Inc.Kraemer Boulevard Brea, CA, United States) and the RNase-Free DNase Set (Cat#79254, QIAGEN, GmBH, Germany). RNA quantity was assessed by UV spectrometry at 260 nm/280 nm absorbance on a spectrophotometer (NanoDrop Technologies, Wilmington, DE, United States).

RNA-seq and differentially expressed gene analysis
The filtered clean reads were mapped to the reference genome database. Each transcript was normalized by fragments per kilobase per million to eliminate the influence of gene length and sequencing depth. The counts of each sample were mapped to the annotated genome after standardization and normalization. Finally, fold change (FC) and difference significance were used to screen the differentially expressed genes (DEGs). Each group of cells was sequenced with three independent biological replicates.

GO and KEGG enrichment analysis
GO term and KEGG pathway enrichment analyses were performed using the tool for Function Annotation in DAVID (https://david.ncifcrf.gov/). The KEGG pathway maps were obtained from the KEGG database (http://www.kegg.jp/).

Expression validation using quantitative polymerase chain reaction
Total RNA was extracted from 1 × 10⁶ cells treated with 1 mL TRIzol. RNA purity and concentration were determined by a NanoDrop 2000 spectrophotometer (Thermo Fisher Scientific). cDNA was synthesized with the ReverTra Ace qPCR Kit (TOYOBO, FSQ-101) and then subjected to quantitative polymerase chain reaction using Power SYBR Green PCR Master Mix (ABI, 4368708). The mRNA levels were determined using 50 ng of cDNA on an Applied Biosystems 7300. All template amplifications were conducted in triplicate with a three-step polymerase chain reaction process. Using Actin as an expression analysis control, the relative expression was calculated using the 2^ΔΔCT method. The primer sequences are provided in Table 1.

Statistical analysis
All numerical data from quantitative polymerase chain reaction are presented as the mean ± SD. Comparisons between groups were performed by the independent sample t-test. Results are presented as the mean ± SD. The Student’s t-test was used to evaluate the difference between the two groups using Prism 8.21 software (GraphPad). The statistical significance level was set at P < 0.05.

## RESULTS

### Identification of DEGs

Differentially expressed lncRNAs and mRNAs \((n = 4)\) are displayed using Volcano plots (Figure 1) and heat maps (Figure 2). The top 20 differentially expressed lncRNAs and mRNAs in the nsPEFs-treated group compared to the control group are listed in Tables 2 and 3, respectively.

In total, 263 DEGs were identified in the PRJNA931816 dataset, of which 92 and 171 were significantly \(|\log2FC| > 0.585\) and \(q < 0.05\) upregulated and downregulated, respectively (Figures 1A and 2A). Of these DEGs, 65 were lncRNAs, of which 36 and 19 were significantly \(|\log2FC| > 1\) and \(q < 0.05\) upregulated and downregulated, respectively (Figures 1B and 2B); 0 were circRNAs (Figure 1C); and 2 were miRNAs, both of which were significantly upregulated (Figure 1D).

### Enrichment analysis of DEGs

To investigate the biological functions and pathways of DEGs, KEGG and GO analyses were conducted for the 263 DEGs. Figure 3 demonstrates the mainly enriched functional annotations from three aspects, including biological processes, cellular components (CC), and molecular functions (MF). From the perspective of biological processes, DEGs were mainly enriched in epithelial cell proliferation, osteoblast differentiation, mesenchymal cell differentiation, nuclear division, and wound healing. From the perspective of CC, DEGs are mainly involved in condensed chromosome, chromosomal region, actin cytoskeleton, and the kinetochore. From the perspective of MF, DEGs are mainly involved in glycosaminoglycan

LncRNA: Long noncoding RNA; FC: Fold change.

binding, integrin binding, nuclear steroid receptor activity, cytoskeletal motor activity, and steroid binding. When the upregulated mRNAs were enriched, 12 mRNAs were found to be involved in chromosome segregation (biological process). For example, among the 12 mRNAs, Top2a is a conserved regulator of chromatin topology which plays an important role in catalyzing reversible DNA double-strand breaks [15]. From the perspective of CC, upregulated mRNAs were mainly enriched in the chromosome, centromeric region, kinetochore, and midbody. From the perspective of MF, upregulated mRNAs were mainly enriched in integrin binding. When the downregulated mRNAs were enriched, they are involved in the extracellular space (CC). Among the 12 mRNAs, Wnt11 encodes a protein that plays an important role in regulating extracellular matrix (ECM) organization [16], and Smoc1 encodes an extracellular glycoprotein that is a critical regulator of cell attachment to the ECM by binding to calcium [17]. From the perspective of GO, downregulated mRNAs were mainly enriched in the positive regulation of gene expression, cell differentiation, and ventricular septum morphogenesis (Figures 3A and C). The detailed relationship between DEGs and GO are shown by the Chord diagram of GO (Figure 3E). GO analysis classified genes heavily involved in epithelial cell proliferation and osteoblast differentiation, among others.

Moreover, KEGG analysis shown in Figures 3B, D, and F demonstrated that DEGs mainly participate in the calcium signaling pathway, ECM-receptor interaction, focal adhesion, and vascular smooth muscle contraction. A Waterfall plot was generated to reveal the potential effects of nsPEFs on signaling pathways (Figure 3F). Other related signaling pathways such as the regulation of actin cytoskeleton, PI3K-Akt signaling pathway, Rap1 signaling pathway, cGMP-PKG signaling pathway, and Hippo signaling pathway-multiple species may also contribute to completing the reaction process of MSCs to nsPEFs. The term cluster showed that nsPEFs may stimulate the cells through the calcium signaling pathway, etc.

Enrichment analysis of differentially expressed lncRNA and miRNAs

The GO enrichment analysis results for the differentially expressed lncRNAs, miRNAs, and mRNAs are shown in Figure 4. Based on the target genes of differentially expressed lncRNAs, the most significantly enriched biological processes were regulation of endothelial cell migration, and ribonucleoprotein complex subunit organization. The most significantly enriched CC were the oligosaccharyltransferase complex, endoplasmic reticulum-Containing complex, chromosome, and centromeric region. The most significantly enriched MF were tubulin binding, nuclear retinoid X receptor binding, and nuclear retinoic acid receptor binding (Figure 4A). Moreover, in Figure 4B, KEGG...
analysis shows that differentially expressed lncRNAs mainly participate in the glycerophospholipid metabolism signaling pathway.

Based on the target genes of differentially expressed miRNAs, the most significantly enriched biological processes were the flavonoid metabolic process, cellular glucuronidation, vesicle fusion to plasma membrane, and animal organ regeneration. The most significantly enriched CC were the intrinsic component of organelle membrane, the integral component of organelle membrane, and the peroxisome. The most significantly enriched MF were glucuronosyltransferase activity, hexosyltransferase activity, and MAP kinase activity (Figure 4C). In addition, KEGG analysis in Figure 4D shows that differentially expressed miRNAs mainly participate in porphyrin metabolism, ascorbate and aldarate metabolism, biosynthesis of cofactors, and the pentose and glucuronate interconversions signaling pathway.

Validation of mRNA expression using quantitative polymerase chain reaction

We confirmed the accuracy of sequencing data for selected mRNAs, and the mRNA validation results were consistent with the RNA-seq data (Figure 5). According to the related signaling pathway, we selected seven upregulated mRNAs, aldehyde dehydrogenase 3 family member A1 (Aldh3a1), centromere protein F (Cep57), kinesin family member 20B (Kif20b), epiregulin (Ereg), Nek2, nuclear receptor subfamily 3 group C member 2 (Nr3c2), and scinderin (Scin). The expression of these seven genes was found to be increased 2.02-fold, 1.8-fold, 2.11-fold, 2.12-fold, 1.66-fold, 2.01-fold, and 2.19-fold, respectively, in nsPEFs-treated cells. We selected six downregulated mRNAs, Actg2, Asic3, Crybat4, Nog, Stxbp5, Tubb2. The expression of these genes was found to be decreased in nsPEFs-treated cells, indicating that the mRNA validation results were consistent with the RNA-seq data.

DISCUSSION

In this study, nsPEFs-treated rMSCs were evaluated by whole transcriptome sequencing in terms of mRNA, lncRNA, circRNA, and miRNA expression. Previous studies have shown that nsPEFs can regulate the expression levels of some mRNAs in MSCs and upregulate the differentiation potential of MSCs[12]. nsPEFs can regulate the chondrogenic differ-
Lin JJ et al. Genetic response of MSCs to nsPEFs

Figure 1 Volcano plots illustrating comparisons of differentially expressed messenger RNAs, long noncoding RNAs, circular RNAs, and microRNAs between each nanosecond pulsed electric field-treated group and the control group. Deminination of MSCs through phosphorylation of molecules of the MAPK signaling pathways[14]. nsPEFs can also regulate the differentiation potential of MSCs through demethylation of stemness genes[12], and can induce nodule formation in osteoblasts[18]. However, the lack of a systematic study hinders further application of nsPEFs in stem cell differentiation.

Using whole transcriptome sequencing, 263 differentially expressed mRNAs (q < 0.05, |log2FC| > 0.585), 2 differentially expressed miRNAs, and 65 differentially expressed lncRNAs were identified, which are involved in stem cell differentiation, calcium ions, plasma membrane, cell skeleton, chromatin, cell adhesion, etc. Our previous study found that nsPEFs (100 ns, 10kV/cm) with specific parameter combinations could promote the chondrogenic, osteoblastic, and adipogenic differentiation of stem cells, but did not induce apoptosis under these parameters[13,15]. Therefore, a combination of 100 ns and 10 kV/cm was selected to conduct electrical stimulation treatment on rMSCs to determine their effects on the gene expression profile. mRNA analysis indicated that nsPEFs may affect cell differentiation, calcium ions, plasma membrane, and other aspects. The expression levels of Scin, Ereg, Kif20b, Aldh3a1, Nr3c2, and Cenpf were upregulated. To better understand the universal effects of nsPEFs on mammalian cells, we compared the gene expression profiles between rMSCs (our data), TM3 cells, Jurkat cells, and U937 cells based on publicly available data[19,20]. We found that the gene expression levels of 23 genes were co-upregulated in rMSCs and TM3 cells, including Kif20b, which indicated that nsPEFs may cause common effects (Supplementary Figure 1). Compared with rMSCs, we found more common DEGs in TM3 cells (23 genes) than in Jurkat cells (3 genes) and U937 cells (6 genes). The reason for this may be that TM3 and rMSCs are adherent cells, and they are from mice or rats, while U937 and Jurkat cells are suspension cells, and are from humans. The 23 common DEGs are involved in the ECM-receptor interaction signaling pathway.

fields were reported to regulate ECM structure[21] and synthesis[22]. On the other hand, the ECM was reported to participate in regeneration[23] and play an important role in stem cell fate[24]. The ECM may be involved in the regulation of cell fate by nsPEFs, which could be further investigated focusing on ECM-receptor interaction. KIF20B was reported to be involved in cell proliferation[25]. Scn belongs to the golgiysin protein superfamily, which is involved in the regulation of cytoskeleton and transport in cell vesicles. It has an important regulatory role in the release of intracellular calcium ions, behaving as a filamentous actin-severing and capping protein[26]. The actin filament network, which in turn leads to the release of secretory vesicles[27], plays an important role in actin-dependent membrane fusion[26]. Ereg belongs to the epidermal growth factor family and is separated from stem cells. It has been reported that Ereg can promote the migration and chemotactic ability of adipose stem cells through the MAPK signaling pathway[28]. Cenpf plays an important role in the microtubule network, which may be related to SNARe proteins which are involved in plasma membrane circulation[29]. These genes remain to be explored in nsPEFs-treated stem cells.

MiRNAs play an important biological function by regulating downstream gene translation. We found that nsPEFs had few effects on miRNAs, and the expression levels of novel.118 and novel.106 were significantly upregulated. GO/KEGG analyses of the target genes of miRNAs showed that nsPEFs may affect vesicle fusion to the plasma membrane, MAPK, etc. In addition, nsPEFs were reported to affect the MAPK signaling pathway by phosphorylation of p38, JNK, and ERK[30]. Bone regeneration can be regulated via the MAPK signaling pathway under specific hydrogel treatment[31]. High-voltage PEFs with short durations, can permeabilize cell membranes with a duration ranging from microseconds to nanoseconds[32]. nsPEFs can also regulate membrane pore formation and upregulate the release of exosomes[33], and vesicle fusion was related to exosome formation[34]. In addition, studies have shown that electroproporation can increase the production of exosomes by increasing intracellular calcium ions[35]. Following nsPEFs treatment, exosome release from tumor cells was also significantly increased[33]. Exosomes, released from stem cells, could stimulate wound regeneration and bone regeneration[36,37]. Thus, nsPEFs may affect exosome formation through vesicle fusion to the plasma membrane in stem cells, which requires further investigation.

Based on the target genes of differentially expressed lncRNAs, the most significant MF involved tubulin binding after nsPEFs treatment and the most significant signaling pathways involved glycerophospholipid metabolism and mismatch repair. In addition, studies have shown that nsPEFs with certain parameters can be applied to regulate the level of cell differentiation[12], promote the release of the intracellular calcium pool[38], and trigger reversible perforation of the cell membrane[39]. A previous study showed that nsPEFs could affect chromosome structure by inducing extracellular release of chromosomal DNA in a calcium-dependent manner[40]. nsPEFs with high intensity (60 kV/cm) can induce damage to the cytoskeleton and nuclear membrane[41]. Chromosome structure is sensitive to physical stimulation. Extremely-low-frequency magnetic fields could stabilize active chromatin, partially depending upon chromatin status[42]. Chromosomes can be oriented, aligned, and translated by high-frequency electric fields, in a frequency-dependent manner[43]. Chromatin accessibility played an important role in gene expression and cell fate[44]. Chromatin undergoes a binary off/on switch during cell fate transitions[45]. Electric fields were reported to change cell fate partially through regulation of calcium and modulation of electrically charged cell-surface receptors in response to the electric field[46]. Thus, nsPEFs may affect the chromatin accessibility and fate of stem cells, which remains to be explored.

The calcium signaling pathway may play an important role in the process of reaction of MSCs to nsPEFs. A previous study showed that nsPEFs could induce calcium flux in osteoblasts[47]. In our study, DEGs and the target genes of lncRNAs and miRNAs were enriched in the calcium signaling pathway as shown by GO/KEGG analyses. Calcium release caused by nsPEFs may be due to nanopore formation in the endoplasmic reticulum[48]. Furthermore, nsPEFs may activate TMEM16F (or anoctamin 6), a protein functioning as a calcium-dependent scramblase, which contributes to the reaction of calcium release due to nsPEFs[49]. BAPTA-AM, a calcium chelator, could attenuate the upregulated phosphorylation level of JNK caused by nsPEFs[14]. Calcium may contribute to apoptosis in hair follicle stem cells through Piezo1[50]. Calcium uptake was reported to control mitochondrial calcium homeostasis and hematopoietic stem cell differentiation, two important determinants in stem cell fate[51]. Calcium-activated potassium channel activity can influence MSC differentiation through membrane potential and intracellular calcium oscillations[52]. Consequently, the calcium signaling pathway may play an important role in the effects caused by nsPEFs in stem cells.

CONCLUSION

There are few studies on the effect of nsPEFs on stem cells at the whole transcriptomic level. The effects of nsPEFs on stem cells were systematically studied, and 263 differentially expressed mRNAs, 2 differentially expressed miRNAs, and 65 differentially expressed lncRNAs were identified. It was shown that nsPEFs may affect stem cells via several signaling pathways and may involve vesicular transport, calcium ion transport, the cytoskeleton, and cell differentiation. Our study is the first to investigate the expression profile of the whole transcriptome in nsPEFs-treated stem cells. This study provides a certain basis for the application of nsPEFs in stem cell differentiation and tissue regeneration.

**ARTICLE HIGHLIGHTS**

**Research background**

Mesenchymal stem cells (MSCs) have been extensively applied in preclinical and clinical research in regenerative medicine. Their differentiation and function are modulated by various exogenous signals, which provide potential strategies for researchers to explore appropriate exogenous signals to regulate the functions and differentiation of stem cells. Nanosecond pulsed electric fields (nsPEFs) represent nanosecond-duration, high-strength electric fields to significantly influence cell phenotypes and regulate stem cell differentiation through multiple pathways. Thus, we used transcriptomics analysis to analyze messenger RNA (mRNA), long noncoding RNA (lncRNA), microRNA (miRNA), and circular RNA (circRNA) expression to identify changes in gene expression following treatment with nsPEFs.
Research motivation
The differentiation and function of MSCs are regulated by nsPEFs. However, the mechanism, especially changes in gene expression after nsPEFs treatment, remains unclear.

Research objectives
To reveal gene expression in MSCs pretreated with nsPEFs and explore the potential gene regulatory mechanism.

Research methods
We used whole transcriptome sequencing to investigate the effects of nsPEFs on MSC transcriptome. Five pulses of nsPEFs (100 ns at 10 kV/cm, 1 Hz) were applied to pretreat MSCs. Total RNA was isolated after pretreatment of MSCs; each transcript was normalized by fragments per kilobase per million. Fold change and difference significance were used to screen the differentially expressed genes (DEGs). Gene Ontology and Kyoto Encyclopedia of Genes and Genomes analyses were conducted to identify gene function, and the results were verified by quantitative polymerase chain reaction.

Research results
The top 20 differentially expressed lncRNAs and mRNAs were revealed. Two hundred and sixty-three DEGs were identified in the PRJNA931816 dataset, of which 92 were upregulated and 171 were significantly downregulated, respectively. DEGs were mainly enriched in epithelial cell proliferation, osteoblast differentiation, mesenchymal cell differentiation, nuclear division, and wound healing. As for cellular components, DEGs were mainly involved in condensed chromosome, chromosomal region, actin cytoskeleton, and the kinetochore. With regard to molecular functions, DEGs are mainly involved in glycosaminoglycan binding, integrin binding, nuclear steroid receptor activity, cytoskeletal motor activity, and steroid binding. Quantitative real-time polymerase chain reaction was used to verify the seven upregulated mRNAs, Aldh3a1, Cenpf, Kif20b, Ereg, Nek2, Nlr3c2, and Scin, and six downregulated mRNAs, Actg2, Asic3, Cryab4, Nog, Stxbp5, and Tubb2b.

Research conclusions
Our systematic investigation of the wide-ranging transcriptional pattern modulated by nsPEFs revealed the differential expression of 263 mRNAs, 2 miRNAs, and 65 lncRNAs. We showed that nsPEFs may affect stem cells via several signaling pathways and involve vesicular transport, calcium ion transport, the cytoskeleton, and cell differentiation.

Research perspectives
This study is the first to investigate the expression profile of the whole transcriptome in nsPEFs-treated stem cells. The findings provide a certain basis for the application of nsPEFs in stem cell differentiation and tissue regeneration.
