Retrospective Study
Factors influencing Frey syndrome after parotidectomy with acellular dermal matrix

Chai XD et al. One year follow-up after parotid surgery

Xian-Da Chai, Huan Jiang, Ling-Ling Tang, Jing Zhang, Long-Fei Yue

Abstract
BACKGROUND
Frey syndrome, also known as ototemporal nerve syndrome or gustatory sweating syndrome, is one of the most common complications of parotid gland surgery. This condition is characterized by abnormal sensations in the facial skin accompanied by episodes of flushing and sweating triggered by cognitive processes, visual stimuli, or eating. This syndrome was first described by Lucie Frey in 1923; however, its precise pathogenesis remains unclear. The incidence rate of Frey syndrome varies greatly, ranging from 4% to 96%, attributed, in part, to differences in the diagnostic criteria for Frey syndrome and differences in methods and techniques used in parotid gland surgery. The primary therapeutic approach is managing associated symptoms. Notably, some researchers have diagnosed Frey syndrome using a minor test and evaluated its severity. Unfortunately, this diagnostic method only assesses subclinical patients without overt clinical symptoms.

AIM
To investigate the preventive effect of acellular dermal matrix (ADM) on Frey syndrome after parotid tumor resection and analyzed the effects of Frey syndrome across various surgical methods and other factors involved in parotid tumor resection.

METHODS
Retrospective data from 82 patients were analyzed to assess the correlation between sex, age, resection sample size, operation time, operation mode, ADM usage, and occurrence of postoperative Frey syndrome.

RESULTS
Among the 82 patients, the incidence of Frey syndrome was 56.1%. There were no significant differences in sex, age, or operation time between the two groups ($P > 0.05$). However, there was a significant difference between ADM implantation and occurrence of Frey syndrome ($P < 0.05$). ADM application could reduce the variation in the incidence of Frey syndrome across different operation modes.

CONCLUSION
ADM can effectively prevent Frey syndrome and delay its onset.

**Key Words:** Parotid gland tumor; Frey syndrome; Acellular dermal matrix; Acellular allogenic dermal matrix

**Core Tip:** The use of acellular dermal matrix in parotid tumor surgery can reduce the incidence of Frey syndrome, especially when the diameter of the surgically removed parotid tissue is greater than 4 cm.
INTRODUCTION
Frey syndrome varies greatly, ranging from 4% to 96%, attributed, in part, to differences in the diagnostic criteria for Frey syndrome and differences in methods and techniques used in parotid gland surgery. The primary therapeutic approach is managing associated symptoms. Notably, some researchers have diagnosed Frey syndrome using a minor test and evaluated its severity. Unfortunately, this diagnostic method only assesses subclinical patients without overt clinical symptoms.

MATERIALS AND METHODS
Research methods
In this retrospective analysis of clinical data from 126 patients who underwent parotid gland surgery in the Department of Oral and Maxillofacial Surgery at Anshun People's Hospital between January 2018 and December 2020, a total of 82 patients were deemed eligible for the study. Patients with parotid gland inflammation, patients who had undergone lymph node dissection, and patients who had undergone periparotid gland surgery during the same period were excluded. All patients provided informed consent for both computed tomography examinations and surgeries. Before the use of ADM, patients were informed regarding the manufacturer, safety, cost, and surgical benefits of ADM. The ADM used was the Hiao B-type oral repair membrane produced by Yantai Zhenghai Biological Technology (registration number: 20153460386).

Surgical method
A modified "S" incision was made in the conventional parotid area. The platysma muscle under the skin was incised, the parotid gland envelope was opened, and the envelope was preserved for tumors that did not invade it. The facial nerve was dissected retrogradely, and any tumor-invading segments of the facial nerve were resected. Partial parotid resection or total parotid lobectomy was performed, depending on the size and location of the tumor. The surgical method randomly categorized the patients into either the partial parotid resection group or the total parotid lobectomy group. The patients
were randomly divided into a tissue patch implantation group and a control group according to their preoperative informed consent and willingness to undergo tissue patch implantation. After surgery, all patients underwent negative pressure ball drainage; for patients with an implanted tissue patch, the drainage tube was placed above the patch according to the product guidelines (Figure 1). Pressure was applied routinely for 14 d after surgery.

Diagnostic criteria for Frey syndrome
Patients were contacted by phone each month after surgery, during which they were questioned regarding symptoms, such as facial flushing, facial paresthesia, and facial sweating during eating. These responses were used to assess Frey syndrome using a subjective questionnaire. Positive Frey syndrome was defined as the presence of any of the four indicators.

Statistical analysis
Data analysis was performed using SPSS (version 25.0) to assess the correlations between age, sex, surgical method, size of surgically removed samples, time of occurrence of postoperative Frey syndrome, and intraoperative application of ADM for the prevention of Frey syndrome. A logistic regression model was established to analyze the risk factors associated with Frey syndrome. Additionally, a receiver operating characteristic (ROC) curve was constructed to predict the diagnostic value of certain risk factors for Frey syndrome. The significance level for the tests was set at $\alpha = 0.05$.

RESULTS
Data of patients with Frey syndrome
A total of 82 patients were included in this study, 46 of whom developed Frey syndrome, an incidence rate of 56.1%. Among them, 43 (52.4%) experienced facial paresthesia after eating, 29 (35.4%) experienced facial flushing after eating, 13 (15.9%) exhibited facial
sweating after eating, and 4 (4.9%) reported that these symptoms seriously affected their daily lives (Table 1).

**Analysis of related Frey syndrome factors**

The 82 patients were categorized into the Frey and non-Frey groups (Table 2). No significant differences were observed in terms of sex, age, or operation time between the two groups. However, a significant difference was noted in the occurrence of Frey symptoms between patients with and without ADM implantation ($P = 0.027$ and $P < 0.05$, respectively). Regarding the surgical methods, no significant difference was observed between the Frey and non-Frey groups ($P = 0.295$); however, there were significant differences in the various surgical approaches without ADM implantation ($P = 0.006$ and $P < 0.05$). All 82 patients were followed up for 16 months postoperatively. In the group with ADM implantation, the median time for Frey symptoms onset was $7.54 \pm 3.2$ months, whereas in the group without ADM implantation, it was $3.43 \pm 2.33$ months; these differences were significant ($P = 0.001$ and $P < 0.05$, respectively).

ROC curve analysis was performed to assess the relationship between the maximum diameter of the surgically resected sample and the occurrence of symptoms of Frey syndrome. The results indicated that the larger the diameter of the resected sample, the higher the probability of Frey syndrome occurrence, with an area under the curve (AUC) of 0.661 (Figure 2).

ROC curve analysis comparing the timing of ADM implantation with the timing of the occurrence of symptoms of Frey syndrome revealed that ADM could significantly delay the occurrence of Frey syndrome, with an AUC of 0.842 (Figure 3).

**DISCUSSION**

Frey syndrome is now commonly believed to be most likely caused by parotid gland surgery or injury. Destruction of parotid gland cyst integrity exposes the parasympathetic branch, which controls the parotid gland acinar secretion in the auriculotemporal nerve issued by the trigeminal nerve within the parotid gland and leads
to its misplacement with the sympathetic nerve, which controls the skin sweat glands. Consequently, upon seeing or eating food, an individual’s parasympathetic branch is stimulated, resulting in secretion from skin sweat glands, leading to facial paresthesia, flushing, or sweating. Frey syndrome occurred in 56.1% of the patients in this study, a rate similar to that reported in most studies. ROC analysis of the tumor sample diameter demonstrated that a resected sample with a larger area was correlated with a higher probability of Frey syndrome occurrence (AUC = 0.661). This finding was consistent with the results presented by Lin et al[112]. Therefore, it was concluded that the probability of Frey syndrome increased when the resected tumor diameter exceeded 4 cm. ADM can effectively prevent the occurrence of Frey syndrome after resection. Favorable outcomes have been achieved using sternocleidomastoid flap and superficial muscle aponeurotic system flap. For the prevention of Frey syndrome. However, it is important to note that the flap preparation process inevitably prolongs the operation time. In this study, there was no significant difference in operation time between the ADM and non-ADM groups, indicating that this method did not extend the operation time in the context of Frey syndrome prevention. Significant differences in the incidence of Frey syndrome were evident among different surgical methods without ADM. Total parotid excision was more likely to result in Frey syndrome, likely because of the removal of excessive parotid tissue that could potentially damage more ototemporal nerve endings. This can contribute to more dislocation-related complications during nerve injury reconstruction. The use of ADM reduced the variability in the occurrence of Frey syndrome between surgical methods. According to the currently available parotid surgery guidelines for benign tumors, preference is given to extracapsular resection or endoscopic minimally invasive surgery to reduce the risk of Frey syndrome. However, in cases of tumors > 4 cm in diameter or located deeper within the parotid gland, total parotid excision combined with ADM to decrease postoperative recurrence and prevent Frey syndrome is recommended.

Regarding the timing of Frey syndrome occurrence, non-implantation of ADM resulted in Frey syndrome occurring approximately 3 months after the operation,
consistent with the neural reconstruction theory that the occurrence time for the middle 
auriculotemporal nerve is abnormal\cite{6}. After ADM implantation, the onset of Frey 
syndrome was delayed by approximately three months. This delay might be attributed 
to the severity of the auriculotemporal nerve injury and the absorption timeframe of the 
ADM.

CONCLUSION

In conclusion, the application of ADM affects Frey syndrome prevention. However, it is 
important to note that ADM degrades within approximately six months, and Frey 
syndrome may still occur after this degradation. Nonetheless, because of the limited 
number of Frey syndrome cases following ADM implantation in this study, the results 
may be biased. Additionally, controlling the diameter of the excised samples can help 
prevent the occurrence of Frey syndrome.
