Intraoperative use of Indocyanine green fluorescence imaging in colorectal surgery

Background: Fluorescence imaging by means of Indocyanine green (ICG) has been applied to intraoperatively determine the perfusion of the anastomosis. The purpose of this Individual Participant Database meta-analysis was to assess the effectiveness in decreasing the incidence of anastomotic leak (AL) after rectal cancer surgery.

Indocyanine green fluorescence imaging in colorectal surgery

Oct 01, 2017 - Indocyanine green fluorescence imaging had been used in the field of hepatobiliary surgery for intraoperative identification of the bile ducts and hepatic tumours for several decades before its application in colorectal perfusion assessment. This imaging modality is emerging as a navigation tool for resection of metastatic hepatic tumours in laparoscopic hepatectomy.
