### ABOUT COVER

Editorial Board Member of *World Journal of Diabetes*, Fernando Cordido, MD, PhD, Full Professor, Department of Medicine, University A Coruña, A Coruña 15006, Spain. Cordido.Carballido@sergas.es

### AIMS AND SCOPE

The primary aim of *World Journal of Diabetes (WJD, World J Diabetes)* is to provide scholars and readers from various fields of diabetes with a platform to publish high-quality basic and clinical research articles and communicate their research findings online. WJD mainly publishes articles reporting research results and findings obtained in the field of diabetes and covering a wide range of topics including risk factors for diabetes, diabetes complications, experimental diabetes mellitus, type 1 diabetes mellitus, type 2 diabetes mellitus, gestational diabetes, diabetic angiopathies, diabetic cardiomyopathies, diabetic coma, diabetic ketoacidosis, diabetic nephropathies, diabetic neuropathies, Donohue syndrome, fetal macrosomia, and prediabetic state.

### INDEXING/ABSTRACTING

The WJD is now abstracted and indexed in Science Citation Index Expanded (SCIE, also known as SciSearch®), Current Contents/Clinical Medicine, Journal Citation Reports/Science Edition, PubMed, and PubMed Central. The 2020 Edition of Journal Citation Reports® cites the 2019 impact factor (IF) for WJD as 3.247; IF without journal self cites: 3.222; Ranking: 70 among 143 journals in endocrinology and metabolism; and Quartile category: Q2.

Abstract

BACKGROUND

The importance of the neuronal microenvironment has been recently highlighted in gut region-specific diabetic enteric neuropathy. Regionally distinct thickening of endothelial basement membrane (BM) of intestinal capillaries supplying the myenteric ganglia coincide with neuronal damage in different intestinal segments. Accelerated synthesis of matrix molecules and reduced degradation of matrix components may also contribute to the imbalance of extracellular matrix dynamics resulting in BM thickening. Among the matrix degrading proteinases, matrix metalloproteinase 9 (MMP9) and its tissue inhibitor (TIMP1) are essential in regulating extracellular matrix remodelling.

AIM

To evaluate the intestinal segment-specific effects of diabetes and insulin replacement on ganglionic BM thickness, MMP9 and TIMP1 expression.

METHODS

Ten weeks after the onset of hyperglycaemia gut segments were taken from the duodenum and ileum of streptozotocin-induced diabetic, insulin-treated diabetic and sex- and age-matched control rats. The thickness of BM surrounding myenteric ganglia was measured by electron microscopic morphometry. Whole-

mount preparations of myenteric plexus were prepared from the different gut regions for MMP9/TIMP1 double-labelling fluorescent immunohistochemistry. Post-embedding immunogold electron microscopy was applied on ultrathin sections to evaluate the MMP9 and TIMP1 expression in myenteric ganglia and their microenvironment from different gut segments and conditions. The MMP9 and TIMP1 messenger ribonucleic acid (mRNA) level was measured by quantitative polymerase chain reaction.

RESULTS

Ten weeks after the onset of hyperglycaemia, the ganglionic BM was significantly thickened in the diabetic ileum, while it remained intact in the duodenum. The immediate insulin treatment prevented the diabetes-related thickening of the BM surrounding the ileal myenteric ganglia. Quantification of particle density showed an increasing tendency for MMP9 and a decreasing tendency for TIMP1 from the proximal to the distal small intestine under control conditions. In the diabetic ileum, the number of MMP9-indicating gold particles decreased in myenteric ganglia, endothelial cells of capillaries and intestinal smooth muscle cells, however, it remained unchanged in all duodenal compartments. The MMP9/TIMP1 ratio was also decreased in ileal ganglia only. However, a marked segment-specific induction was revealed in MMP9 and TIMP1 at the mRNA levels.

CONCLUSION

These findings support that the regional decrease in MMP9 expression in myenteric ganglia and their microenvironment may contribute to extracellular matrix accumulation, resulting in a region-specific thickening of ganglionic BM.

Core Tip: These findings demonstrate an intestinal segment-specific thickening of basement membrane (BM) surrounding myenteric ganglia. In diabetes, ganglionic BM is thickened in the ileum, but not in the duodenum. Insulin prevented the diabetes-related BM thickening. The matrix degrading matrix metalloproteinase 9 (MMP9) expression was decreased in myenteric ganglia and its environment in the diabetic ileum, however, it remained unchanged in the duodenum. Similarly, MMP9/Tissue inhibitor of metalloproteinase 1 (TIMP1) ratio decreased only in ileal myenteric ganglia. Intestinal segment-specific induction of MMP9 and TIMP1 messenger ribonucleic acid levels was revealed. Regionally decreased MMP9 expression in ganglia correlates well with segment-specific thickening of ganglionic BM and these coincide with region-dependent enteric neuronal damage.

INTRODUCTION

In the last few years, there has been an increasing emphasis on the importance of the neuronal microenvironment in the diabetic damage of the enteric nervous system[1-3]. Moreover, the region-specific susceptibility of enteric neurons to diabetic neuropathy and their sensibility to immediate insulin treatment[4,5] serve as further motivation to thoroughly investigate the molecular neural milieu in different intestinal segments.

INTRODUCTION

In the last few years, there has been an increasing emphasis on the importance of the neuronal microenvironment in the diabetic damage of the enteric nervous system[1-3]. Moreover, the region-specific susceptibility of enteric neurons to diabetic neuropathy and their sensibility to immediate insulin treatment[4,5] serve as further motivation to thoroughly investigate the molecular neural milieu in different intestinal segments.
Since enteric ganglia are not vascularized, the capillaries in close vicinity have a critical role to supply them with oxygen and nutrients[6]. It is well established that among others, the thickened endothelial basement membrane (BM) is one of the earliest histological hallmarks of diabetic microangiopathy contributing to impaired permeability function in retina or renal glomeruli[7-11]. Consistent with this, we revealed a strictly intestinal region-dependent thickening and separation of capillary BM in type 1 diabetic rat model[12]. Structural and morphological findings (e.g., opened endothelial tight junctions, enlarged caveolar compartments, impaired distribution of endogenous albumin) suggesting altered permeability of intestinal capillaries in the vicinity of myenteric ganglia were also revealed[12].

There may be several reasons for capillary BM thickening. On the one hand, the diabetes-related enhanced expression of the prevalent BM components leads to thickened BM. High glucose-induced overexpression of collagen IV, fibronectin, laminin, agrin and tenascin was observed in different models[10,13-16]. On the other hand, due to the long-lasting hyperglycaemic condition, the decreased degradation of these BM components may also result in a thickened BM, even under good glycaemic control. In rats with diabetic nephropathy, the decreased metalloprotease activity promotes the accumulation of collagen IV in the matrix[17]. Others also observed an accelerated matrix accumulation in metalloprotease knockout mice[18]. Overall, the accumulation of extracellular matrix (ECM) molecules and/or the decreased degradation of matrix components may contribute to the imbalance in ECM dynamics and lead to BM thickening.

ECM proteins are degraded by several proteinases[19]. Among them, metalloproteinases (MMPs) are the most essential in regulating ECM remodelling[19]. Matrix metalloproteinases (MMPs) are calcium-dependent zinc-containing endopeptidases[20]. The MMP family has more than 20 members in vertebrates, most of them with basic three-domain structures and different ECM and other targets[21]. However, MMPs have not only proteinase activity, but are also implicated in other essential functions, like releasing apoptotic ligands, cytokine inactivation, cell proliferation and differentiation, angiogenesis, and host defense[19,21-23].

MMP9 is secreted by a wide variety of cells, such as macrophages, smooth muscle cells, endothelial cells, and it is one of the most extensively studied enzymes involved in ECM breakdown and turnover. Due to the crosstalk between ECM and inflammatory processes, MMPs are associated with the development of diabetic microvascular complications in different organs[24]. MMP activation accelerates apoptotic processes in retina[25]. There is correlation also between upregulated MMP expression and the progression of diabetic nephropathy[26,27]. Under diabetic conditions, MMP expression is influenced by high glucose level and reactive oxygen species[27]. Moreover, the endogenous tissue inhibitors of metalloproteinases (TIMPs), are crucial to determine the optimal proteolytic activity of MMPs[28]. Among the four members of TIMP family, TIMP1 has the strongest efficiency to inhibit most of the MMPs[29]. TIMPs can directly restrict MMP-dependent matrix proteolysis or indirectly facilitate ECM accumulation[29].

All enteric ganglia are surrounded with a continuous BM[6,30], and the components of this ECM sheet are not detectable inside the enteric ganglia[31]. Several studies dealt with the composition and alterations of ECM in the intestinal wall due to its impact on enteric ganglion formation during development[32-34]. The appropriate matrix composition is indispensable for the development of enteric ganglia and normal nerve fibre function[33,35]. The relevance of different BM abnormalities was investigated in Hirschprung’s disease[36-38], however, little is known about its role in other pathological processes, like diabetes-related enteric neuropathy.

We assume that structural and molecular alterations involved in maintaining the dynamic structure of ECM in the intestinal wall may contribute to the gut region-dependent diabetic neuropathy. Therefore, the primary goal of this study was to evaluate the effects of type 1 diabetes and immediate insulin replacement on BM thickness surrounding myenteric ganglia in different gut segments. Furthermore, we aimed to investigate the intestinal region-dependent expression of MMP9 and TIMP1 in myenteric ganglia and their microenvironment in control, diabetic and insulin-treated diabetic rats.

**MATERIALS AND METHODS**

**Animal model**

Adult male Wistar rats (Crl: WI BR; Toxi-Coop Zrt.) kept on standard laboratory chow
(Farmer-Mix Kft., Hungary) and with free access to drinking water, were used throughout the experiments. The rats, weighing 200-300 g, were divided randomly into three groups: streptozotocin (STZ)-induced diabetics (n = 4), STZ-induced diabetics with insulin treatment (n = 4) and sex- and age-matched controls (n = 4). The controls were treated with vehicle, while hyperglycaemia was induced by a single intraperitoneal injection of STZ (Sigma-Aldrich, Hungary) at 60 mg/kg as described previously[4,12]. The animals were considered diabetic if the non-fasting blood glucose concentration was higher than 18 mmol/L. From this time on, the insulin-treated hyperglycaemic group received a subcutaneous injection of insulin (Humulin M3; Eli Lilly Nederland, Netherlands) each morning (2 IU) and afternoon (2 IU). Equivalent volumes of saline were given subcutaneously to the rats in the diabetic and the control group. The blood glucose level and weight of each animal were measured weekly during the 10-wk experimental period. Those STZ-induced diabetic animals which recover spontaneously or their blood glucose level decreased under 18 mmol/L during the 10-wk experimental period did not participate in this study.

The animal protocol was designed to minimize pain or discomfort to the animals. The animals were acclimatized to laboratory conditions (23 °C, 12 h/12 h light/dark, 50% humidity, ad libitum access to food and water) for 2 wk prior to experimentation.

In all procedures involving experimental animals, the principles of the National Institutes of Health (Bethesda, MD, United States) guidelines and the EU directive 2010/63/EU for the protection of animals used for scientific purposes were strictly followed, and all the experiments were approved by the National Scientific Ethical Committee on Animal Experimentation (National Competent Authority), with the license number XX./1636/2019.

**Tissue handling**

Ten weeks after the onset of hyperglycaemia, the animals were euthanized by barbiturate overdose (150 mg/kg pentobarbital sodium i.v. injection) for tissue collection. The gut segments of the control, STZ-induced diabetic, and insulin-treated diabetic rats were dissected and rinsed in 0.05 mol/L phosphate buffer (PB; pH 7.4). Samples were taken from the duodenum (1 cm distal to the pylorus) and the ileum (1 cm proximal to the ileo–caecal junction), and processed for fluorescent immunohistochemistry, quantitative electron microscopy and quantitative polymerase chain reaction (qPCR). For double-labelling fluorescent immunohistochemistry, samples (2-3 mm) from different gut segments were fixed in 4% paraformaldehyde (PFA) and embedded in melted paraffin. For electron microscopic studies, small pieces (2-3 mm) of the gut segments were fixed in 2% PFA and 2% glutaraldehyde solution and then further fixed for 1 h in 1% OsO₄. After rinsing in buffer and dehydrating in increasing ethanol concentrations and acetone, they were embedded in Embed812 (Electron Microscopy Sciences, United States). The Embed blocks were used to prepare ultrathin (70 nm) sections, which were mounted on nickel grids and processed for morphometrical study and immunogold labelling. For qPCR study, the 3-cm-long gut segments were cut along the mesentery and pinned flat. The layer of mucosa and submucosa was removed, and the residual material (myenteric plexus and intestinal smooth muscle layers) was snap-frozen in liquid nitrogen and stored at -80 °C until use.

**Double-labelling fluorescent immunohistochemistry**

For double-labelling immunohistochemistry, paraffin-sections (3.5 µm) derived from different gut segments were immunostained with MMP9 and TIMP1. Briefly, after blocking in TRIS-buffered saline (TBS) containing 1% bovine serum albumin and 10% normal goat serum, the sections were incubated overnight with anti-MMP9 (mouse monoclonal immunoglobulin G (IgG); Abcam, UK; final dilution 1:100) and anti-TIMP1 (rabbit polyclonal IgG; Santa Cruz Biotechnology, United States; final dilution 1:50) primary antibodies at 4 °C. After rinsing in buffer and dehydrating in increasing ethanol concentrations and acetone, they were embedded in Embed812. For electron microscopic studies, small pieces (2-3 mm) of the gut segments were fixed in 2% PFA and 2% glutaraldehyde solution and then further fixed for 1 h in 1% OsO₄. After rinsing in buffer and dehydrating in increasing ethanol concentrations and acetone, they were embedded in Embed812. For double-labelling fluorescent immunohistochemistry, samples (2-3 mm) from different gut segments were fixed in 4% paraformaldehyde (PFA) and embedded in melted paraffin. For electron microscopic studies, small pieces (2-3 mm) of the gut segments were fixed in 2% PFA and 2% glutaraldehyde solution and then further fixed for 1 h in 1% OsO₄. After rinsing in buffer and dehydrating in increasing ethanol concentrations and acetone, they were embedded in Embed812. After embedding, the blocks were sectioned and mounted on nickel grids for electron microscopy. For fluorescent microscopy, paraffin-sections (3.5 µm) were cut and mounted on slides for immunostaining. The sections were incubated with anti-MMP9 (mouse monoclonal immunoglobulin G (IgG); Abcam, UK; final dilution 1:100) and anti-TIMP1 (rabbit polyclonal IgG; Santa Cruz Biotechnology, United States; final dilution 1:50) primary antibodies at 4 °C. After washing in TBS with 0.025% Triton X-100, sections were incubated with secondary antibodies for 1 h at room temperature. Negative controls were performed by omitting the primary antibody when no immunoreactivity was observed. Sections were observed and photographed with a Zeiss Imager Z.2 microscope equipped with an AxioCam 506 mono camera.
Transmission electron microscopy

Morphometric study: For ultrathin sectioning, four Embed blocks were used for each intestinal segment and each condition (control, STZ-induced diabetics, and insulin-treated diabetics). Three grids per block were counterstained with uranyl acetate (Merck, Germany) and lead citrate (Merck, Germany) and were examined and photographed with a JEOL JEM 1400 transmission electron microscope. Montage photographs of twelve myenteric ganglia per intestinal segment per condition were made at a magnification of 20000 × and the thickness of the BM were measured at random points around the ganglia with the help of a limited size (700 nm × 700 nm) grid net. The mean thickness was calculated for each ganglion by using the AnalySIS 3.2 program (Soft Imaging System GmbH, Germany).

Post-embedding immunohistochemistry

The Embed blocks used previously for the electron microscopic morphometry also served for the MMP9 and TIMP1 post-embedding immunohistochemistry. Ultrathin sections from each block were sequentially incubated overnight in anti-MMP9 mouse monoclonal IgG (Abcam, United Kingdom; final dilution 1:50) or anti-TIMP1 rabbit polyclonal IgG (Santa Cruz Biotechnology, United States; final dilution 1:50) primary antibodies, followed by colloidal gold conjugated anti-mouse IgG (conjugated to 18 nm colloidal gold; Jackson Immunoresearch, United States; final dilution 1:20) or anti-rabbit IgG (conjugated to 18 nm colloidal gold; Jackson Immunoresearch, United States; final dilution 1:20) secondary antibodies for 3 h, with extensive TBS washing in-between. The specificity of the immunoreaction was assessed in all cases by omitting the primary antibodies in the labelling protocol and incubating the sections only in the gold conjugated secondary antibodies. Sections were counterstained with uranyl acetate (Merck, Germany) and lead citrate (Merck, Germany) and were examined and photographed with a JEOL JEM 1400 transmission electron microscope. The quantitative properties of gold particles coding for MMP9 or TIMP1 were determined in the myenteric ganglia, the endothelium of capillaries in the vicinity of these ganglia and the intestinal smooth muscle cells. Counting was performed on digital photographs at a magnification of 20000 × with the AnalySIS 3.2 program (Soft Imaging System GmbH, Germany). Montage pictures of twelve ganglia, the entire endothelial profile of eleven well-oriented capillaries and eleven field of view of the surrounding smooth muscle cells per intestinal segment per condition were used. The intensity of the labelling was expressed as the total number of gold particles per unit area.

RNA preparation, reverse transcription and qPCR

Intestinal tissue samples were homogenized in RNA Bee reagent (Tel-Test Inc., United States) and total RNA was prepared according to the procedure suggested by the manufacturer. For assessing RNA concentration and purity, the absorbance of RNA samples was measured at 260 and 280 nm using NanoDrop 1000 UV/VIS Spectrophotometer (Thermo Scientific, United States). The RNA concentration was calculated using the A260 = 1.0 equivalent to approximately 40 g/mL single-stranded RNA equation. The A260/A280 ratio approximately 1.9 was accepted for clean RNA. First-strand cDNA was synthesized by using 2.5 µg total RNA as template, 200 pmol of each dNTP (Thermo Scientific, United States), 200 U Maxima H Minus Reverse Transcriptase (Thermo Scientific, United States) and 500 pmol random hexamer primers (Sigma-Aldrich, Hungary) in a final volume of 20 µL, and incubated for 10 min at 37 °C, followed by 45 min at 52 °C. Real-time qPCR was performed for gene expression studies, using Luminaris Color HiGreen Low ROX qPCR Master Mix (Thermo Scientific, United States) in Applied Biosystems 7500 Real-Time PCR System (Life Technologies, Hungary). The qPCR reactions were carried out with a temperature program of 10 min at 95 °C (initial denaturing), followed by 45 cycles of 15 s at 95 °C; 30 s at the annealing temperature 63 °C followed by a melting curve stage with temperature ramping from 60 to 95 °C and a final cooling for 30 s at 40 °C. The quantities of examined messenger ribonucleic acid (mRNAs) were normalized to that of 18 S ribosomal RNA, and gene expression was calculated in terms of 2^\text{ΔΔCt} method[59].

Primers

Primers were designed based on the data bank entries. For normalization of the amounts of MMP9 and TIMP1 mRNA, the 18 S mRNA level was used as internal standard. MMP9 2F: 5′ CTCTACACGGGACGCGCAACG 3′; MMP9 2R: 5′ CGGTGGTGCGCACCAGGG 3′.TIMP1 2F: 5′ ACAGGTTCCTCCGTTCCGCTAC 3′;
TIMP1 2R: 5’ CTGCAGGCACTGAGTGGCAA 3’. 18S F: 5’ GAAACGGCTACATCCAAGG 3’; 18S R: 5’ CCGCTCCCAAGATCCAACTACG 3’.

Statistical analysis
Statistical analysis was performed with Kruskal-Wallis test, and Dunn’s multiple comparisons test (electron microscopic study), or one-way analysis of variance with Newman-Keuls test (Table 1 and qPCR study). Statistical analysis of RT-qPCR reactions for each animal were performed in triplicate to increase the reliability of the measurements. All analyses were carried out with GraphPad Prism (GraphPad Software, United States). A probability of \( P < 0.05 \) was set as the level of significance.

RESULTS

Disease characteristics of diabetic and insulin-treated diabetic rats
The general characteristics of the STZ-induced diabetic and insulin-treated diabetic, as well as the control animals are shown in Table 1. Untreated diabetic rats were characterized by a significantly reduced body weight and a markedly increased blood glucose concentration (26.23 ± 1.89 mmol/L) as compared to the sex-and age-matched controls (5.99 ± 0.19 mmol/L). In the immediate insulin replacement group, the body weight of the animals was similar to controls by the end of the experiment. The blood glucose concentration of insulin-treated rats (7.13 ± 1.37 mmol/L) remained at the control level during the 10 wk experimental period.

Morphometry of the BM surrounding myenteric ganglia
Myenteric ganglia are surrounded by a thin BM, which delimits the ganglia from the adjacent tissues. The collagen fibrils located in the extracellular space never enter into the ganglia (Figure 1A).

In controls, BM thickness was the same in the proximal and distal part of the small intestine (approximately 34-36 nm), however, a region-specific thickening was revealed in diabetic rats. The ganglionic BM was significantly thicker in the diabetic ileum relative to control values (44.04 ± 1.62 nm vs 34.85 ± 1.11 nm, \( P < 0.0001 \)), whereas in the duodenum it did not exceed that of the controls (Figure 1B).

Although the diabetes-related BM thickening was prevented by immediate insulin treatment in the ileum, the BM was significantly thinner (26.98 ± 0.93 nm) in this region in insulin-treated rats (Figure 1B).

Presence of MMP9 and TIMP1 immunoreactivity in the gut wall
Double-labelling fluorescent microscopy revealed MMP9 and TIMP1 immunoreactivity in myenteric ganglia and their environment (Figure 2). The intensity of the fluorescent labelling varied among different structures of the gut wall: it was the lowest in the ganglia, higher in the intestinal blood vessels, and pronouncedly intense in the circular and longitudinal smooth muscle layers (Figure 2).

Quantitative changes in MMP9 expression in different cellular compartments
The expression of MMP9 was further demonstrated by gold-labelling immunoelectron microscopy in myenteric ganglia, endothelial cells of capillaries in the vicinity of these ganglia and smooth muscle cells (Figure 3). The 18 nm gold particles indicating MMP9 were often detected in cytosol, nuclei, intracellular organelles of the neuronal perikaryon (Figure 3A) and neuropil region (Figure 3B) of the ganglia, caveolar compartments, and plasma membrane of endothelial and smooth muscle cells (Figure 3C).

In control animals, the density of MMP9-labeling gold particles was significantly higher in the myenteric ganglia of the ileum than in the duodenal segment (\( P < 0.001; \) Figure 4A). Also, higher ileal density of MMP9 particles was observed in endothelial and smooth muscle cells (data not shown separately, but visible on Figure 5B and C).

In diabetic rats, the number of MMP9-labeling gold particles significantly decreased in the myenteric ganglia (Figure 5A), capillary endothelium (Figure 5B) and intestinal smooth muscle (Figure 5C) of the ileum. The greatest decrease has been observed in the endothelial cells of diabetics, where the number of MMP9 particles was more than half of the controls (0.75 ± 0.11 vs 1.66 ± 0.26). The immediate insulin treatment only partially prevented the diabetes-related alterations in MMP9 expression. However, in the diabetic duodenum, the number of MMP9 gold particles did not change in the myenteric ganglia or in the other cell types in either of the experimental groups.

Figure 1 Representative electron micrograph of a myenteric ganglion from an insulin-treated diabetic rat. A: The myenteric ganglion is surrounded by basement membrane (BM) (arrows). Scale bar: 500 nm; B: Quantitative evaluation of BM thickness in different gut segments of control, diabetic, and insulin-treated diabetic rats. The thickening of BM surrounding myenteric ganglia remained unchanged in the duodenum, however it increased significantly in the ileum of diabetic rats. Immediate insulin treatment prevented BM thickening in the ileum. aP < 0.0001 (relative to the controls); bP < 0.0001 (between diabetics and insulin-treated diabetics).

Figure 2 Representative fluorescent micrograph of a paraffin section of myenteric ganglia from the ileum of a control rat after matrix metalloproteinase 9-tissue inhibitor of metalloproteinase 1 double-labeling immunohistochemistry. A: Matrix metalloproteinase 9 immunoreactivity is indicated in red; B: tissue inhibitor of metalloproteinase 1 immunoreactivity is shown in green; and C: The merge is depicted on. Scale bar: 20 μm. MG: Myenteric ganglia; LSM: Longitudinal smooth muscle layer; CSM: Circular smooth muscle layer; arrows—blood vessels.

Quantitative changes in TIMP1 expression and MMP9/TIMP1 ratio

TIMP1 displayed a quite low, but region-dependent expression in the myenteric
**Figure 3** Representative electron micrographs subjected to matrix metalloproteinase 9 post-embedding immunohistochemistry. A: Myenteric ganglia from a control duodenum; B: A diabetic ileum; and C: Capillary endothelium and intestinal smooth muscle from a control duodenum. The 18 nm gold particles (arrows) indicating matrix metalloproteinase 9 were observed in cytosol, nuclei or in association with intracellular organelles and plasma membrane. Scale bars: 500 nm. P: Neuronal perikaryon; N: Nucleus; SMC: Smooth muscle cell; EC: Endothelial cell; LU: Capillary lumen.

**Figure 4** Quantitative changes in MMP9 and TIMP1 expression. A: Quantitative evaluation of matrix metalloproteinase 9 (MMP9); and B: Quantitative evaluation of tissue inhibitor of metalloproteinase 1 (TIMP1) labelling gold particles in myenteric ganglia from different gut segments of control rats. In control conditions, the number of MMP9 particles was significantly higher, while TIMP1-labeling was significantly lower in the distal part of the small intestine. Data are expressed as means ± SEM. *P < 0.01 and **P < 0.001 (between control duodenum and control ileum).

There were no significant differences in the distribution of TIMP1 gold particles between different intestinal regions in other control cell types (data not shown). In addition, neither the hyperglycaemia nor the immediate insulin treatment resulted in any significant alterations in the number of TIMP1-labeling gold particles in either of the cellular compartments (data not shown).
Figure 5 Quantitative changes in matrix metalloproteinase 9 expression in different cellular compartments. A: Quantitative evaluation of matrix metalloproteinase 9 (MMP9)-labeling gold particles in myenteric ganglia; B: Capillary endothelium; and C: Intestinal smooth muscle cells from different gut segments of control, diabetic, and insulin-treated diabetic rats. In diabetics, the number of MMP9-labeling gold particles was significantly decreased in all cellular compartments of the ileum, while it was unchanged in the duodenum relative to controls. The number of gold particles was closer to the control values after immediate insulin treatment. Data are expressed as means ± SEM. $^aP < 0.05$ and $^bP < 0.01$ (relative to controls).

However, a region-specific MMP9/TIMP1 ratio was observed in the myenteric ganglia. While the MMP9/TIMP1 ratio remained unchanged in the duodenum, the decrease in the ratio was nearly 50% in the ileal ganglia of diabetic rats (Figure 6). The MMP9/TIMP1 ratio was more than double in the duodenum, while it was close to the control value in the ileum in the insulin-treated group (Figure 6).

**Quantitative alterations in mmp9 and timp1 mRNA expression**

The expression level of MMP9 mRNA markedly increased in both gut segments under chronic hyperglycaemic conditions. The rate of induction was approximately 5.5-fold in tissue homogenates prepared from the diabetic duodenum, and approximately 7.0-fold in the diabetic ileum relative to controls and normalized to the endogenous 18S RNA as reference (Figure 7).

In parallel, TIMP1 mRNA expression was highly upregulated (approximately 5-fold) in tissue homogenates originating from the ileum, while it remained unchanged in duodenal homogenates of diabetic rats (Figure 7).

**DISCUSSION**

In accordance with our principle findings that diabetic myenteric neuropathy is intestinal region-dependent[4], and that the neuronal microenvironment is also suffering from a series of strictly region-specific diabetic damages[12,40], the present study provides more evidence of gut segment-specific, diabetes-related alterations of the ECM biology in myenteric ganglia, intestinal capillaries and smooth muscle of the gut wall.

We have shown for the first time that the BM surrounding myenteric ganglia is regionally thickened along the small intestine. The thickness was increased by more than 25% in the ileum, while it was unchanged in the duodenum of diabetic rats.
Figure 6 The ratio of matrix metalloproteinase 9 and tissue inhibitor-labeling gold particles in myenteric ganglia of different gut segments of control, diabetic, and insulin-treated diabetic rats. In diabetic rats, the matrix metalloproteinase 9/tissue inhibitor of metalloproteinase 1 ratio was not altered in duodenal, but was markedly decreased in ileal ganglia. The immediate insulin replacement did not restore the equilibrium ratio observed in controls.

Figure 7 Fold change in the messenger ribonucleic acid levels of matrix metalloproteinase 9 and tissue inhibitor of metalloproteinase 1 genes, measured by real-time fluorescence-based quantitative polymerase chain reaction using the $2^{ΔΔCt}$ method. Data sets are presented as the fold change in gene expression normalized to the endogenous reference (RNA18S) and relative to the untreated controls. Data are expressed as means ± standard deviation. *P < 0.001 and **P < 0.0001.

Using the same type 1 diabetic rat model, we formerly demonstrated that the endothelial BM of intestinal capillaries supplying the enteric ganglia displayed similar structural alterations[12]. The thickening and separation of capillary BM was pronounced in the distal part of the gastrointestinal tract, but not in the duodenum of diabetics[12], which suggests optimal and very stable conditions in the duodenum while a more susceptible microenvironment is plausible in the ileum along the proximal-distal axis of the gut. Other findings include increased amount of ECM proteins (laminin-1 and fibronectin), as well as BM thickening of the small intestinal smooth muscle cells in diabetic rats[41], and also significant thickening of perineurial cell BM and loss of myelinated nerve fibres in diabetic peripheral neuropathies[42-44]. The immediate insulin replacement prevented diabetes-related BM thickening surrounding the ileal myenteric ganglia, as it inhibited the BM thickening of capillary endothelium[12] or reversed the hyperglycaemia-induced ECM accumulation in the intestinal smooth muscle layers[41]. Among the underlying mechanisms of ECM accumulation resulting in both ganglionic and endothelial BM thickening, the matrix degrading metalloproteinases have become the focus of the present study. We have shown that MMP9 and TIMP1 is present in myenteric ganglia and their environment using fluorescent and electron microscopy. The ultrastructural localization of these markers within the cytoplasm and nuclei of the enteric neurons, endothelial and smooth muscle cells was in agreement with other findings[45,46]. The nuclear localization of MMPs may have a role in regulation the activity of DNA-repairing and apoptotic proteins[47,48].
Quantitative immunogold labelling showed that the MMP9 particle density increased, while the TIMP1 particle density decreased in myenteric ganglia along the proximal-distal axis of the small intestine under control conditions. In addition to this opposite tendency, we observed that the particle density of TIMP1 was an order of magnitude lower than that of MMP9. In diabetic rats, the MMP9-indicating gold particles decreased in all cell types of the ileum, however, they remained unchanged in all duodenal compartments. Moreover, the MMP9/TIMP1 ratio was also decreased only in the ileal ganglia, but not in the duodenum. Immediate insulin replacement prevented diabetic alterations only in part as it was described in other studies[4,5,12].

The region-dependent BM thickening and changes in MMP production in different cellular compartments correlate well with each other. In the diabetic ileum, the decrease in MMP9 expression both in myenteric ganglia, and endothelial and smooth muscle cells suggests a decreased breakdown of ECM components resulting in ECM accumulation and thickening of BM around the myenteric ganglia and also the intestinal capillaries[12]. However, in the diabetic duodenum, where MMP9 production remained optimal in all cell types, the thickness of ganglionic and endothelial BM also remained unchanged[12].

Although we did not observe significant changes in the distribution of TIMP1 protein-detecting gold particles in different cell types under diabetic conditions and after insulin treatment, the segment-specific induction of both MMP9 and TIMP1 mRNA expression was demonstrated. Meanwhile, the MMP9 induction was not accompanied by altered TIMP1 expression in the duodenal tissue homogenates of diabetics, however, in the ileal samples, a 7-fold increase in MMP9 mRNA level was detected, along with a great upregulation in TIMP1 mRNA expression. The regulation of MMPs/TIMP's expression and activity is complex, involving both transcriptional and post-transcriptional mechanisms using multiple signal pathways, microRNA modulation, post-translational modifications and extracellular inhibition[21,49-51]. Based on these findings, we presume that despite of the MMP9 transcriptional alterations, due to post-transcriptional modifications[49], the balance in the production of MMP9 and TIMP1 proteins was retained in the duodenum, which contributes to the maintenance of optimal ECM dynamics in this segment. In contrast, in the ileum, not only MMP9 but also TIMP1 transcription was highly upregulated, resulting in MMP9 protein underproduction and ECM accumulation. Inconsistent alterations of MMP9 mRNA and protein expression presuming post-transcriptional regulation were also observed in diabetic nephropathy[52]. Moreover, upregulated microRNA production resulted in decreased MMP9 expression, which in turn contributed to renal fibrosis in diabetic kidney[52,53]. Decreased matrix degradation due to increased MMP mRNA level, but decreased activity was also documented in diabetic nephropathy[17,54], modulated by advanced glycation end products[55]. Increased fibrosis was also demonstrated in MMP knockout mice[18]. In contrast, some studies report that MMP overexpression promotes renal fibrosis due to a possible interplay with TIMPs[51,56], while others revealed that MMP2 and MMP9 triggered mitochondrial damage and apoptotic processes in retinal capillaries[57-59].

However, it certainly seems that the imbalance in MMP/TIMP ratio[60,61] caused by various molecular mechanisms disturbs the equilibrium of ECM degradation and turnover and contributes to several inflammatory processes, as well as vascular or neuronal damage, which requires further investigations.

CONCLUSION

Overall, in the present study, we provided evidence that the region-dependent thickening of ganglionic basement membrane is closely related to the regionally decreased MMP9 expression in myenteric ganglia and its environment, coinciding with the intestinal region-specific enteric neuropathy in type 1 diabetes.

ARTICLE HIGHLIGHTS

Research background
The diabetic damage of enteric neurons and intestinal capillaries supplying the enteric ganglia are strictly intestinal region dependent. Therefore, the underlying molecular differences in the neuronal environment should be more emphasized.
**Research motivation**
To prove the presence of essential regional differences in the neuronal milieu which may explain the gut segment-specific enteric neuropathy and vascular dysfunction.

**Research objectives**
To reveal the impact of diabetes and immediate insulin treatment on the thickness of basement membrane (BM) surrounding myenteric ganglia, as well as the expression of matrix metalloproteinase 9 (MMP9) and its tissue inhibitor of metalloproteinase 1 (TIMP1) which are key players in regulating extracellular matrix dynamics.

**Research methods**
Electron microscopic morphometry, fluorescent and gold-labelling immunohistochemistry and quantitative polymerase chain reaction were applied to study the myenteric ganglia and their environment in the different gut segments of diabetic, insulin-treated diabetic and control rats.

**Research results**
In the diabetic ileum, the ganglionic BM was significantly thickened which was prevented by insulin treatment. These changes were also reflected in a decrease in MMP9/TIMP1 ratio in ileal myenteric ganglia. However, in the duodenum of diabetics neither the ganglionic BM thickness nor the MMP9/TIMP1 ratio were changed.

**Research conclusions**
Regionally decreased MMP9 expression in ganglia and region-dependent ganglionic BM thickening correlate well with intestinal segment-specific enteric neuropathy.

**Research perspectives**
Based on these findings in type 1 diabetic rat model, we are planning to expand our investigations to type 2 diabetes in the future.

**ACKNOWLEDGEMENTS**
We thank Erika Németh and Katalin Arany for the excellent technical assistance.
