ABOUT COVER

Peer-reviewer of World Journal of Clinical Cases, Prof. Adrián Ángel Inchauspe, obtained his MD in 1986 from La Plata National University (Argentina), where he remained as Professor of Surgery. Study abroad, at the Aachen and Tubingen Universities in Germany in 1991, led to his certification in laparoscopic surgery, and at the Louis Pasteur University in Strasbourg France, led to his being awarded the Argentine National Invention Award in 1998 for his graduate work in tele-surgery. He currently serves as teacher in the Argentine Acupuncture Society, as Invited Foreigner Professor at the China National Academy of Sciences and Hainan Medical University, and as editorial member and reviewer for many internationally renowned journals. (L-Editor: Filipodia)

AIMS AND SCOPE

The primary aim of World Journal of Clinical Cases (WJCC, World J Clin Cases) is to provide scholars and readers from various fields of clinical medicine with a platform to publish high-quality clinical research articles and communicate their research findings online.

WJCC mainly publishes articles reporting research results and findings obtained in the field of clinical medicine and covering a wide range of topics, including case control studies, retrospective cohort studies, retrospective studies, clinical trials studies, observational studies, prospective studies, randomized controlled trials, randomized clinical trials, systematic reviews, meta-analysis, and case reports.

INDEXING/ABSTRACTING

The WJCC is now indexed in Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports/Science Edition, PubMed, and PubMed Central. The 2020 Edition of Journal Citation Reports® cites the 2019 impact factor (IF) for WJCC as 1.013; IF without journal self cites: 0.991; Ranking: 120 among 165 journals in medicine, general and internal; and Quartile category: Q3.

Abstract

BACKGROUND
In most cases, it is not difficult to differentiate common bile duct (CBD) stone from Ascaris infection because they are different disease entities and have different imaging findings. The two diseases usually demonstrate unique characteristic findings on computed tomography or magnetic resonance cholangiopancreatography. However, we report a rare case from our experience in which a CBD stone mimicked and was misdiagnosed as Ascaris.

CASE SUMMARY
A 72-year-old male presented with elevated serum liver enzymes. Computed tomography showed a hyper-attenuated, elongated lesion in the CBD lumen and associated biliary inflammation. Magnetic resonance cholangiopancreatography and endoscopic retrograde cholangiopancreatography revealed a linear filling defect in the bile duct. Moreover, elongated echogenic material with a central hypoechogenic area was seen on endoscopic ultrasound. Although the imaging findings caused us to suspect infection with the nematode Ascaris, the lesion was revealed to be a dark-brown-colored CBD stone through endoscopic extraction.

CONCLUSION
We report a rare case of a CBD stone that mimicked Ascaris. We also review the literature for side-by-side comparisons of the imaging features of CBD stones and ascariasis.

Key Words: Case report; Common bile duct; Gallstones; Ascaris; Ascariasis; Multidetector computed tomography; Magnetic resonance cholangiopancreatography
Core Tip: Although common bile duct stone and Ascaris are not commonly discussed as differential diagnosis each other, they can be misunderstood in case of the elongated common bile duct stone. We should be able to learn the differential points through this case.

INTRODUCTION

Choledocholithiasis, or common bile duct (CBD) stones, is a relatively common disease, and 10% to 15% of people with gallstones also have stones in the bile duct\[1,2\]. Biliary stones usually have angulated shapes or lamellated appearances and commonly accompany biliary inflammation. CBD stones are not difficult to diagnose when they manifest as high-density lesions in the distal CBD lumen without enhancement on computed tomography (CT) and when they demonstrate biliary filling defects with relatively low signal intensity on T2-weighted images of magnetic resonance (MR) cholangiography\[2\].

However, Ascaris infection can complicate diagnosis of choledocholithiasis. Although its incidence has been decreasing, ascariasis is still an important cause of hepatobiliary disease in Asia, Africa, and South America. The worms are usually found in the intestinal lumen, but they occasionally move into the bile duct and gallbladder through the ampulla of Vater\[3\]. Diagnosis of hepatobiliary ascariasis can be made by visualizing the larvae in the biliary tree, as they may manifest as a cylindrical filling defect with or without movement on imaging studies\[4\].

Usually, there is little confusion in differentiation of CBD stone and Ascaris since they are different disease entities with different imaging manifestations. However, we report a case of a CBD stone that mimicked and was misdiagnosed as Ascaris lumbricoides.

CASE PRESENTATION

Chief complaints

A 72-year-old male visited our outpatient clinic with elevated liver enzymes.

History of present illness

He did not complain of any symptoms.

History of past illness

He had been previously admitted to our hospital for a liver abscess about 10 years prior, when he had visited our outpatient clinic.

Physical examination

There were no remarkable signs, and his vital signs were normal.

Laboratory examinations

Laboratory values revealed conspicuous elevation of alkaline phosphatase and gamma-glutamyl transpeptidase (γ-GT) in addition to mild elevation of serum amylase.

Imaging examinations

On CT (Figure 1A and B), a hyper-attenuated, thin, linear-shaped lesion was found in the lumen of the distal CBD. In addition, dilated intrahepatic bile ducts and periductal enhancement on the arterial phase suggested inflammatory changes of the intrahepatic bile duct. MR cholangiopancreatography (MRCP; Figure 1C and D) revealed a thin, linear filling defect in the lumen of the dilated CBD that had low signal intensity on
Figure 1  A 72-year-old male with a distal common bile duct stone mimicking Ascaris. A and B: Coronal reformatted images of contrast-enhanced computed tomography showed a hyperattenuated, elongated lesion inside the distal common bile duct (CBD) lumen (arrows); C and D: A T2-weighted coronal image revealed a linear filling defect in the distal CBD lumen with mild ductal dilatation, findings that mimic an Ascaris worm; E and F: An elongated tubular filling defect was seen on endoscopic retrograde cholangiopancreatography, and a hyperechoic lesion with a central hypoechoic area was seen on endoscopic ultrasound; G: A dark-brown-colored CBD stone was discovered through endoscopic removal.

T2-weighted images, and the findings were sufficient to diagnose a parasitic larva, such as Ascaris. Subsequently, endoscopic retrograde cholangiopancreatography (ERCP) demonstrated a tubular filling defect in the dilated CBD (Figure 1E), and a linear, hyperechoic lesion with a central low-echoic area was seen on endoscopic ultrasound (EUS) (Figure 1F).

MULTIDISCIPLINARY EXPERT CONSULTATION

After removal by an endoscopic procedure, the lesion was found to be a tubular-shaped CBD stone (Figure 1G).
FINAL DIAGNOSIS
The final diagnosis was CBD stone.

TREATMENT
The patient was treated with antibiotics for three days and was discharged without any complications (Figure 2).

OUTCOME AND FOLLOW-UP
Subsequent follow-up blood tests conducted at an outpatient clinic showed gradual decrease in the abnormal liver function test values.

DISCUSSION
Unless it is radiolucent, a CBD stone is not difficult to diagnose on CT. Biliary stones can appear in various attenuations on CT, and only about 20% show high attenuation\(^5\). Most biliary stones are either round or amorphous-shaped. In addition to the imaging findings from the biliary stone itself, low attenuated bile surrounding the stone and associated ductal dilatation or narrowing can improve the likelihood of correct diagnosis of biliary stone\(^5\). In addition, a signal void in the CBD or a fluid level with low signal intensity in the dependent portion of the CBD on MR imaging can suggest a CBD stone\(^6\). Even though ERCP is an invasive procedure, it has the benefit of simultaneous diagnosis and treatment\(^7\). Moreover, EUS has excellent diagnostic ability when it is performed with ERCP, and a biliary stone can be characteristically seen as a hyperechoic lesion accompanying a posterior acoustic shadow in the CBD on EUS\(^8,9\).

On the other hand, Ascaris can appear as an elongated, high-density structure in the biliary tree on CT, although this modality is only used as complementary for diagnosis\(^6\). On MR cholangiogram, Ascaris demonstrates a “double-tube” appearance, a hypointense tubular defect inside the CBD with central hyperintense material representing the fluid-filled gut of the worm\(^10\). On ERCP, the worm is seen as an intraductal filling defect with motility in the bile duct\(^4,11\). The difference between CBD stone and Ascaris is even more obvious on EUS, in which the parasite appears as a spherical-shaped hyperechogenic lesion without posterior acoustic shadowing\(^12\).

To the best of our knowledge, there has been only one case report of CBD stone mimicking *Ascaris lumbricoides*, and the report only described the sonographic findings\(^11\). Thus, it is not thought to be difficult to distinguish CBD stone from Ascaris infestation on imaging or clinical findings. Although they share radiologic findings of a non-enhancing high-density lesion on CT and a filling defect on T2-weighted images on MR, these two diseases rarely are part of the same differential diagnoses because their typical presentations are different. However, if these typical imaging features are not seen, differential diagnosis for tubular structures in the CBD could be confusing. Although we had never previously experienced an elongated-shaped CBD stone, we did experience an ascariasis patient who manifested similar imaging findings to the present case (Supplementary Figure 1).

In the present case, not only did the stone appear very similarly shaped to an Ascaris worm on CT and MR cholangiography, but it was also mistaken for Ascaris on EUS due to its elongated shape with a central hypoechoic area, rather than the nodular or angular appearance of a typical CBD stone. However, Ascaris could have been distinguished from a CBD stone in the present case by the relatively longer (15-49 cm) and thicker (2-6 mm in females)\(^13\) body size of Ascaris compared to CBD stones, even if no motility was observed\(^14\).

Although this was a rare case of CBD stone mimicking biliary ascariasis, it serves as a reminder that patients complaining of biliary colic or imaging finding of an elongated filling defect occupying the CBD should not be diagnosed by shape alone, and a CBD stone can mimic biliary Ascaris.
CONCLUSION

Although CBD stone and Ascaris are not commonly discussed in the same differential diagnosis, they can be confused in cases with an elongated CBD stone.
