Valve repair after infective endocarditis secondary to perforation caused by *Streptococcus gordonii*

A case report and literature review

Yifan Qu, Jun Yang, Junyu Wang, Bing Wei, Xinghua Ye, Yixuan Li, Sili Han
Abstract

BACKGROUND
We report a case of infective endocarditis in a patient with congenital heart valve lesions accompanied by infective endocarditis (IE), which was diagnosed based on blood culture analysis that revealed the presence of a gram-negative bacterium, *Streptococcus gordonii*.

CASE SUMMARY
The patient had a history of precordial valve disease diagnosed by cardiac ultrasound[Ed1], as well as a four-month history of fever. He was subjected to comprehensive anti-infection and anti-heart failure treatment in the internal medicine department. Further examination revealed sudden dislodgement from and perforation through the aortic valve by the superfluous organisms[Ed2], as well as occurrence of bacterial emboli dislodgement, which caused bacteraemia and infectious shock. He recovered and was discharged from the hospital after surgical and postoperative anti-infection treatments.

CONCLUSION
we review the treatment process and highlight inspirations and reflections from this case. Suggest possible future changes in treatment modalities

**Key Words:** Bacteraemia, comprehensive medical and surgical treatment, *Streptococcus gordonii*, infective endocarditis (IE), case report

**Core Tip:** Infective endocarditis is caused by pathogenic bacteria that infect the heart *via* the bloodstream. It is most common in heart valves but also in atrioventricular walls, tendons and other structures. Congenital heart disease is common in heart structures near the abnormal intracardiac shunt low-pressure cavities, and serious cases can be accompanied by abscesses, fistulas and other cardiac complications. The fallen flab can cause embolism of various organs throughout the body, it has a high mortality rate, and there are no specific clinical manifestations. It is very easy to misdiagnose, and missed diagnoses are common. The search for sensitive diagnostic methods and timely treatment are particularly important.

**INTRODUCTION**

Infective endocarditis (IE) is a life-threatening cardiovascular disease with an annual incidence of 1.5/100,000-15/100,000 and a mortality rate of 20%-25%[1]. The disease is caused by a pathogenic microorganism that directly infects heart valves, the endocardium of the ventricular wall or the endocardium of the adjacent aorta *via* the bloodstream, often leading to superfluous organisms. Subacute IE is characterized by an insidious and slow onset, with a long course that usually lasts between 6 wk and 3 mo[2]. These patients mostly experience cardiac problems. Due to the insidious site of infection, notably, IE patients have diverse and nonspecific clinical manifestations, which subsequently lead to missed diagnoses and misdiagnoses that result in serious adverse consequences that threaten quality of life[3]. Therefore, early diagnosis coupled with timely treatment is crucial for management of the disease. In the present study, we report a case of IE caused by *Streptococcus gordonii*, with fever as the main manifestation, at our hospital.

**CASE PRESENTATION**

*Chief complaints*

A 61-year-old man presented at our hospital with intermittent fever and malaise for 4 mo.
History of present illness

Four months before the visit, he had developed a fever (up to 40°C), mostly in the afternoon and at night, accompanied by chills and malaise. Although his body temperature normalized after three days of anti-infection treatment via self-treatment, the fever reappeared after stopping the treatment. The disease progressively worsened, and his blood pressure decreased and was accompanied by an increased heart rate. The patient was diagnosed with infectious shock and was subsequently transferred to our hospital for further treatment.

2

History of past illness

The patient was previously in good health

Personal and family history

He was previously healthy and had no family history of disease.

Physical examination

Physical examination revealed slightly pale skin and mucous membranes, with no enlargement of the jugular vein[Ed1], but there was enlargement of the cardiac border to the left. There was also evidence of a grade III-IV diastolic murmur in the aortic valve area and peripheral vascular signs (+).

Laboratory examinations

Laboratory test results revealed normal leukocytes and neutrophils, the patient had C-reactive protein and calcitonin levels of 53.1 mg/L and 2.66 ng/mL, respectively, as well as liver and renal function tests that were within normal limits. The PPD test results were negative. Paired blood cultures (asymmetric limbs, e.g., left upper limb and right lower limb) on three consecutive days showed gram-positive cocci. Macrogenetic test GNS showed Streptococcus gordonii.
**Imaging examinations**
Cardiac ultrasonography showed an EF of 52% and aortic valve leaflet thickening and echogenic enhancement, moderate regurgitant signal under the aortic valve in diastole, small amount of regurgitant signal on the left atrial side of the mitral valve in systole, small amount of regurgitant signal on the right atrial side of the tricuspid valve in systole, an ascending aortic internal diameter of 46 mm, an aortic valve Vmax of 2.2 m/s, an enlarged left atrium, aortic valve calcification moderate regurgitation, and mild regurgitation of the second and tricuspid valves. The cardiac [Ed1] MRI results were consistent with dilated cardiomyopathy changes, left heart insufficiency, a significantly reduced systolic function, aortic valve thickening and stenosis, incomplete closure of the mitral valve and tricuspid valve, a small amount of pericardial effusion, pericardial inflammatory changes, and a small amount of bilateral pleural effusion.

**Bone marrow aspiration**
Flow cytometry showed an increase in the proportion of granulocytes and nucleated red cells and a mild decrease in the proportion of lymphocytes. The phenotype was not abnormal. Abnormal immunoglobulins and identification of multiple myeloma: Immunofixation electrophoresis (IFE) results showed that there was no "M protein" detected within the serum polyclonal immunoglobulins; there were no kap and lam light chain "M protein" detected in the urine[Ed1]. Serum protein and immunofixation electrophoresis revealed no significant "M protein", a reduction in albumin levels, and elevated levels of α1 and γ globulins. The serum IgG, IgA, IgM and kap, as well as lam light chain levels, were normal, but the IgE levels were high. We also found a moderate increase in the level of urine kap light chain and 24-hour urine protein levels. Protein electrophoresis revealed no specific band in the urine. No light chain type "M protein" was detected in the urine via immunofixation electrophoresis, while bone marrow aspiration revealed normal results. The results excluded multiple myeloma.
FINAL DIAGNOSIS
Infective endocarditis

TREATMENT
The patient's prolonged unexplained fever, coupled with blood culture and echocardiographic results, made us strongly suspect a subacute infection. The patient's fever subsided after 9 days of continuous treatment, and his infection index was under control. Consequently, aortic valve replacement was recommended following anti-infection treatment. The patient then developed preoperative sudden onset of chest and abdominal pain with profuse sweating. An emergency transoesophageal ultrasonography was performed. The results are presented in Figure 3. In summary, we found evidence of aortic valve redundancy with perforation, while the emergency CTA results revealed moderate stenosis of the lumen at the beginning of the abdominal trunk. The possibility of bacterial [Ed1]oesophageal involvement and visible penetrating ulcers was considered (Figure 4). Consequently, the surgical approach was changed from simple aortic valve replacement to aortic valve replacement surgery and aortic valvuleplasty. The intraoperative examination findings were as follows: moderate levels of yellowish pericardial fluid were present, there was marked widening of the ascending aorta, marked malformation of the aortic bicuspid valve, leaflet destruction with perforation and massive regurgitation, complete leaflet removal, and compression of the artificial vessel to wrap the ascending aorta, and placement of aortic valve bioprosthesis was performed[Ed2]. The operation was successfully completed. Postoperative pathological analysis revealed fibrous connective tissue hyperplasia with focal glassy and mucinous degeneration, localized fibrin deposition, and evidence of calcified foci in the valve tissue.

OUTCOME AND FOLLOW-UP
The patient received anti-infection treatment for one month after surgery. Reexamination revealed that his liver, kidney and cardiac functions had been restored back to normal.

**DISCUSSION**

In 2016, the American Association for Thoracic Surgery (AATS) published an expert consensus on the surgical management of infective endocarditis, the most recent guiding document for the management of this condition. The AATS expert consensus indicates that the current DUKE criteria, which are based on the diagnostic criteria proposed in 1994 and have subsequently been modified several times, are the most practical for the diagnosis of IE[1]. The most common clinical IE manifestation is fever, with an insidious onset in subacute cases, and it can be associated with relatively mild toxic symptoms that may range from weeks to months[Ed1]. Although IE is a common cause of unexplained fever, only 18.6%-20.3% of patients present with typical manifestations described in the DUKE criteria, such as skin petechiae, emboli, splenomegaly, and Osler nodules. Approximately 30% of IE patients do not exhibit an obvious heart murmur during the early stages of disease development or during the course of treatment. The doctors who treated the patient in the present study before he came to our hospital thought that the heart murmur could be explained by mitral regurgitation and did not consider the possibility of IE. Notably, they were satisfied with improvement of his clinical symptoms and did not follow up on the disease change, a phenomenon that resulted in a delay of treatment of the disease[Ed2].

Bacteraemia, caused by pathogenic microorganisms in the blood, is the basis for the development of IE. Blood culture tests have diagnostic value and can help guide the selection of anti-infective drugs. The main pathogens and major routes of infection in IE have changed in recent years. Notably, virulent and drug-resistant staphylococci are the most common organisms and are more likely to occur in elderly patients, as well as in those with nosocomial chronic disease and intracardiac implants. In the present study, the blood culture results suggested that this patient had a *Streptococcus gordonii*
infection. This pathogen belongs to the Gram-stain-positive retarded streptococcal group and is a partly anaerobic α-haemolytic streptococcus (VGS). Recent studies have shown that community-acquired autologous valvular endocarditis caused by VGS is also common in IE patients, particularly in developing countries[5], and many of them are caused by Streptococcus gordonii. Generally, S. gordonii colonizes the oral cavity and upper respiratory tract and is mainly involved in the composition of dental plaque; it is a conditional pathogen that is usually not pathogenic. In recent years, many cases of S. gordonii infections have been reported in China and abroad, and these cases include cases of sepsis, IE, splenic abscess and septic arthritis. These infections have subsequently been associated with poor oral hygiene, loose teeth, dental surgery and other invasive procedures. The patient in the present study exhibited upper respiratory tract infection symptoms, such as a sore and dry throat, 1 wk before the onset of fever. However, he did not pay attention to these symptoms and had overexertion during the same period[6]. It is worth noting that the patient’s medical history is imperative to obtain an adequate disease diagnosis[Ed3].

Echocardiography is a key procedure for confirming an IE diagnosis[7] because it can not only detect superfluous organisms at an early stage but also accurately measure their sizes, thereby facilitating assessment of the disease severity, could be used to cardiac function, and can detect cardiac complications, among other factors[Ed4]. However, echocardiography is influenced by subjective factors. In the present case, the initial echocardiography failed to detect superfluous organisms in this patient’s heart valve and relaxed vigilance. We attributed this to the fact that the location and size of the flab were not easily detectable by the ultrasound beam and because of the physician’s inexperience. Transoesophageal echocardiography can detect redundant organisms with a diameter of 1-1.5 mm and directly reveal the relationship between the redundant organisms and the valve from the posterior left atrium, achieving a positive detection rate of up to 90%. However, echocardiography is not an ideal detection tool for patients with severe valvular lesions, bulging valves <2 mm, prolapsed valves, or
valves without bulging valves. Based on this, a negative result does not completely exclude IE.

Successful IE treatment depends on efficient removal of pathogenic microorganisms, and surgery has shown promise in successfully eradicating these patients[Ed5][9]. Previous studies have shown that to reduce morbidity and mortality, 20-50% of patients require cardiac surgery[Ed6] to remove infected tissue and restore valve function[10-12]. In fact, timely surgery is the only hope for saving a patient's life in a case of severe IE. Internal medicine and surgery have their own advantages and shortcomings during IE treatment. Although internal medicine-based treatments can clear most of the microorganisms, it was not efficacious in the patient in this case. The use of anti-infection treatment not only caused an impairment of his cardiac function but also resulted in haemodynamic abnormalities due to the destruction of the intracardiac structures and the emergence of dislodged bacterial emboli. Therefore, internal medicine treatment alone cannot prevent the occurrence of superfluous events, necessitating the application of surgical treatment that corrects congenital valve malformation and restores the heart valve. The patient in the current study was subjected to surgical treatment, which corrected his congenital valve malformation, restored his heart valve function, and improved his heart failure. The patient recovered.

Choosing the right time for surgery is the key to effective surgical treatment. It is generally believed that patients with heart failure or haemodynamic disorders, persistent infections, uncontrolled intracardiac local infections, refractory microbial infections, persistent flabby biology >10 mm with embolism or valve dysfunction should undergo surgery as soon as possible[13]. The echocardiography results of the patient in the present study revealed a flabby biology measuring 1.2 cm * 1.2 cm, with indications for surgery. There are also physicians who believe that surgical intervention is not appropriate in the acute phase due to the possibility of an increased occurrence of complications and high surgical risks and believe in conservative therapy. [Ed7] Notably, controversy still surrounds the timing and indications for surgery, necessitating further research explorations with large randomized controlled clinical
trials. Although the application of cardiac surgery for the treatment of active infective endocarditis is only a century old, recent advances in surgical techniques and perioperative management have made it the cornerstone of IE treatment. Moreover, there is no uniform standard for the indication, timing, and risk assessment of surgery in active IE due to the complexity and variable nature of the disease[14]. Therefore, clinical decision-making in complex cases must be fully individualized, taking into account the patient's demographic characteristics, comorbidities, disease severity, and stage, to determine whether and when to perform surgical intervention and to prepare for foreseeable risks after surgery. There is a need to consult hospitals with multidisciplinary teams specializing in IE in cases of complex IE. Given the large number of IE patients in China, there is a need for concerted efforts across clinical research to standardize IE treatment strategies by focusing on unresolved international issues. Since the population and pathogenic spectrum of IE patients in China are different from those in Europe and the United States, there is a need to develop active IE surgery strategies for the Chinese population.

CONCLUSION

1. Infective endocarditis is characterized by an insidious onset, a difficult diagnosis, an aggressive condition and susceptibility to flabby dislodgement events. Therefore, patients with recurrent fever of unknown origin need to be monitored closely[Ed1].

2. There is a need for clinicians to raise awareness of IE, especially by performing comprehensive physical examinations and analysis. Clinicians should highly consider IE in patients with unexplained fever, especially those with underlying cardiac disease conditions.

3. Patients, who are suspected of having IE but who have negative results on echocardiogram should be retested or operated on by a senior ultrasonographer. In cases where transthoracic echocardiogram suggests indirect hints, such as valve prolapse, incomplete closure, or septic lesions, transoesophageal echocardiogram should be performed promptly to improve the detection rate.
The disease course in patients with active IE is often complex and variable. Although international guidelines have somewhat standardized the indications and timing of surgery in active IE patients, there is still a need for concerted efforts from an IE-specific multidisciplinary team during decision-making for specific patients. In fact, the discussion on the indication and timing of surgery is a game of risk vs expected benefit. Therefore, assessment of the risk of surgery in active IE patients is imperative for effective management of the disease.

ACKNOWLEDGEMENTS
I am grateful to Dr. Jun Yang and Dr. Junyu Wang for inspiring me about the treatment of infective endocarditis and establishing a sound examination idea. I am grateful to Bing [Ed1] Wei, Silu Han, Yixuan Li, and Xinghua Ye for organizing the case contents and providing helpful examination results.
