ABOUT COVER
Editorial Board Member of World Journal of Gastrointestinal Surgery, Ali Coskun, MD, Associate Professor, Doctor, Department of General Surgery, Izmir Bozyaka Training and Research Hospital, Izmir 35380, Turkey. dralicoskun3564@hotmail.com

AIMS AND SCOPE
The primary aim of World Journal of Gastrointestinal Surgery (WJGS, World J Gastrointest Surg) is to provide scholars and readers from various fields of gastrointestinal surgery with a platform to publish high-quality basic and clinical research articles and communicate their research findings online.

WJGS mainly publishes articles reporting research results and findings obtained in the field of gastrointestinal surgery and covering a wide range of topics including biliary tract surgical procedures, biliopancreatic diversion, colectomy, esophagectomy, esophagostomy, pancreas transplantation, and pancreatectomy, etc.

INDEXING/ABSTRACTING
The WJGS is now abstracted and indexed in Science Citation Index Expanded (SCIE, also known as SciSearch®), Current Contents/Clinical Medicine, Journal Citation Reports/Science Edition, PubMed, and PubMed Central. The 2021 edition of Journal Citation Reports® cites the 2020 impact factor (IF) for WJGS as 2.582; IF without journal self cites: 2.564; 5-year IF: 3.378; Journal Citation Indicator: 0.53; Ranking: 97 among 212 journals in surgery; Quartile category: Q2; Ranking: 73 among 92 journals in gastroenterology and hepatology; and Quartile category: Q4.

Retrospective Study

Laparoscopic vs open surgery in ileostomy reversal in Crohn’s disease: A retrospective study

Jian Wan, Xiao-Qi Yuan, Tian-Qi Wu, Mu-Qing Yang, Xiao-Cai Wu, Ren-Yuan Gao, Lu Yin, Chun-Qiu Chen

Abstract

BACKGROUND

Although minimally invasive surgery is becoming more commonly applied for ileostomy reversal (IR), there have been relatively few studies of IR for patients with Crohn’s disease (CD). It is therefore important to evaluate the potential benefits and risks of laparoscopy for patients with CD.

AIM

To compare the safety, feasibility, and short-term and long-term outcomes of laparoscopic IR (LIR) vs open IR (OIR) for the treatment of CD.

METHODS

The baseline characteristics, operative data, and short-term (30-d) and long-term outcomes of patients with CD who underwent LIR and OIR at our institution between January 2017 and January 2020 were retrieved from an electronic database and retrospectively reviewed.

RESULTS

Of the 60 patients enrolled in this study, LIR was performed for 48 and OIR for 12. There were no statistically significant differences in baseline characteristics, operation time, intraoperative blood loss, duration of flatus and soft diet, postoperative complications, hospitalization time, readmission rate within 30 d, length of hospitalization, hospitalization costs, or reoperation rate after IR between the two groups. However, patients in the LIR group more frequently required lysis of adhesions as compared to those in the OIR group (87.5% vs 41.7%, respectively, \( P < 0.05 \)). Notably, following exclusion of patients who underwent enterectomy plus IR, OIR was more advantageous in terms of postoperative recovery of gastrointestinal function and hospitalization costs.

ORCID number: Jian Wan 0000-0002-5922-2375; Xiao-Qi Yuan 0000-0002-4954-3426; Tian-Qi Wu 0000-0002-0103-4806; Mu-Qing Yang 0000-0002-4982-7186; Xiao-Cai Wu 0000-0001-7546-6882; Ren-Yuan Gao 0000-0002-7602-0601; Lu Yin 0000-0002-9060-0178; Chun-Qiu Chen 0000-0002-4248-7414.

Author contributions: Wan J reviewed the literature and drafted the manuscript; Yuan XQ and Wu TQ contributed to data analysis; Wan J, Yuan XQ, Wu TQ, Yang MQ, Yin L, and Chen CQ performed the surgery; Chen CQ, Wu XC, and Gao RY made revision to the manuscript; all authors have approved the submission of this manuscript.

Institutional review board statement: The study protocol was approved by the Ethics Committee of the Shanghai Tenth People’s Hospital Affiliated to the Tongji University School of Medicine (approval No. 21K53).

Informed consent statement: Given that the research was retrospective, the requirement for informed patient consent was waived.

Conflict-of-interest statement: The authors declare that there is no conflict of interest regarding the publication of this article.
CONCLUSION
The safety and feasibility of LIR for the treatment of CD are comparable to those of OIR with no increase in intraoperative or postoperative complications.

Key Words: Crohn’s disease; Laparoscopy; Ileostomy reversal; Intestinal adhesion; Enterolysis; Faster recovery

Core Tip: Laparoscopic surgery has been shown to promote faster recovery, decrease postoperative pain and morbidity, and improve postoperative quality of life. For Crohn’s disease (CD) patients who require IR, laparoscopy greatly improves the rate of enterolysis and reduces the incidence of ileus. Meanwhile, laparoscopy can effectively explore the entire gastrointestinal tract to identify strictures within short segments of the small bowel, while avoiding large incisions. The aim of the present study was to compare the operative data and short-term and long-term outcomes of laparoscopic ileostomy reversal vs open ileostomy reversal to explore the safety and feasibility of laparoscopic ileostomy reversal for CD.

INTRODUCTION
A temporary ileostomy is frequently created during low colorectal anastomosis to prevent fistula formation. After intestinal anastomosis, patients with active Crohn’s disease (CD) are at a greater risk for anastomotic fistula formation, which often requires ileostomy[1,2] to alleviate symptoms. Given the proclivity for recurrence, ileostomy reversal (IR) is limited to relatively few CD patients[3]. However, as compared with colostoma, ileostoma requires more complex care and is associated with a greater risk for complications[4]. Therefore, in the remission stage of CD, many patients consider IR. Normally, open IR (OIR) is not overly complicated. But, the varying degrees of intestinal adhesions in CD require intraoperative enterolysis[5]. In addition, with the progression of CD, the whole digestive system will inevitably become fibrotic, eventually leading to stricture[6]. Therefore, it is essential to check the whole gastrointestinal tract during IR for patients with CD.

Previous studies have shown that laparoscopic surgery promotes faster recovery, decreases postoperative pain and morbidity, and improves postoperative quality of life[5,7,8]. During open surgery for CD, surgeons often have to explore the entire gastrointestinal tract to avoid missing occult diseased segments and critical proximal strictures. Laparoscopy can effectively explore the entire gastrointestinal tract to identify strictures within short segments of the small bowel, while avoiding large incisions. Although laparoscopy has become more commonly applied in IR[9], relatively few studies have compared OIR with laparoscopic IR (LIR) for CD. It is therefore important to evaluate the potential benefits and risks of LIR in patients with CD. The aim of the present study was to compare the operative data and short-term and long-term outcomes of LIR vs OIR to explore the safety and feasibility of LIR for CD.

21K53) and conducted in accordance with the tenets of the Declaration of Helsinki. The cohort of this retrospective study consisted of 60 patients who underwent IR at our institution from January 2017 to January 2020. Of these 60 patients, LIR was performed for 48 and OIR for 12. The inclusion criteria were age 18-75 years and pathological confirmation of CD. All procedures were performed by two experienced laparoscopic colorectal surgeons. Standardized treatment regimens were used during the perioperative period. The following data were retrieved from the electronic database of Shanghai Tenth People’s Hospital: Age, gender, body mass index (BMI), American Society of Anesthesiologists (ASA) physical status classification, duration of ileostomy, duration of CD, history of abdominal surgery, hematologic parameters (WBC, CRP, ESR, ALB, HB, PLT, PT, and APTT), operation time, intraoperative blood loss, enterolysis rate, days to flatus and soft diet, postoperative complications, hospitalization time, readmission rate within 30 days, length of stay, and hospitalization cost. As a long-term outcome, the reoperation rate after IR was determined by telephone interviews.

Preoperative preparation
Preoperative preparation included physical examination, computed tomography, magnetic resonance imaging, ultrasonography, and colonoscopy. Patients in the remission stage of CD were considered for IR.

Surgical procedure
Laparoscopy was performed using the four-port method. Briefly, two transverse sites below the umbilicus were punctured with 12-mm trocars for observation, the right abdomen was punctured with a 5-mm trocar, and the left abdomen was punctured with 5- and 12-mm trocars. The entire gastrointestinal tract was explored laparoscopically to separate the intraperitoneal adhesions at the stoma and the distal intestinal stump (Figure 1A-C). Following incision of the annulus of the skin around the stoma, the stoma and distal intestinal stump were pulled out. If the bowel segment was obviously fibrotic with a stricture, strictureplasty or resection of the strictured segment was performed. The proximal and distal intestines were anastomosed side to side with auto sutures (GIA 80 mm; Medtronic plc, Dublin, Ireland). Then, the openings were closed and the anastomosis was reinforced with 3-0 absorbable sutures. For open surgery, an incision was made directly along the skin around the stoma. Then, the stoma and distal intestinal stump were separated under direct visualization. The anastomosis method was the same as that in the laparoscopic group.

Statistical analysis
All data analyses were conducted using IBM SPSS Statistics for Windows, version 24.0. (IBM Corporation, Armonk, NY, United States) and GraphPad Prism version 8.0 (GraphPad Software Inc., San Diego, CA, United States). Quantitative data are expressed as the mean ± SD (range). Data were compared using the Student’s t-test and chi-squared test. A probability (P) value of < 0.05 was considered statistically significant.

RESULTS
Baseline characteristics
There were no statistically significant differences in age, gender, BMI, ASA class, duration of ileostomy, CD duration, history of abdominal operation, or hematologic examination between the LIR and OIR groups (P > 0.05) (Table 1).

Characteristics of intraoperative and postoperative observation indexes
Postoperative recovery, operation time, intraoperative blood loss, and days to flatus and soft diet were similar between the two groups. Enterolysis was required for 42/48 (87.5%) patients in the LIR group and 5/12 (41.7%) in the OIR group (P < 0.05). However, when cases of enterectomy combined with IR were excluded, OIR was still advantageous for patients with CD. In those cases, OIR was superior to LIR in terms of days to flatus (1.7 ± 0.7 d vs 2.3 ± 0.6 d, respectively, P < 0.05), days to soft diet (2.7 ± 0.7 d vs 4.5 ± 1.7 d, respectively, P < 0.05), and hospitalization costs (37301 RMB vs 57967 RMB, respectively, P < 0.05) (Table 2). There was no significant difference in postoperative complications between the LIR and OIR groups (10.4% vs 16.7%, respectively). One patient in the LIR group developed an anastomotic fistula after

surgery and recovered after continuous double-cannula irrigation, which explains why one patient in the LIR group was hospitalized for 32 d. Another patient developed anastomotic bleeding, which was resolved after hemostasis treatment. One patient with ileus recovered after conservative treatment. Two patients developed incisional infections in both the LIR and OIR groups and recovered after periodic dressing change. As a long-term outcome, the reoperation rate after IR was similar between the LIR and OIR groups. One patient in the LIR group and one in the OIR group underwent enterectomy again at 22 and 24 mo, respectively (Figure 2).

DISCUSSION

The aim of this retrospective study was to compare the feasibility, safety, and short-term and long-term outcomes of LIR vs OIR for CD. The results showed that LIR is a safe and feasible technique with acceptable outcomes and, thus, is worthy of further promotion and clinical study.

For high-risk intestinal anastomosis, the use of prophylactic ileostomy can significantly reduce the incidence of anastomotic leakage[10,11]. However, enterostomy is often associated with many complications due to improper management. According to multiple studies, the overall stoma complication rate ranges from 12% to 72%, with the most common complications being retraction, hernia, prolapse, peristomal skin problems, and necrosis, which severely affect the psychosocial status of the patient and the ability to return to normal daily activities[12-14]. Restoration of intestinal continuity by IR is an ideal strategy to improve quality of life. In recent decades, laparoscopic techniques have become increasingly widely applied in gastrointestinal surgery[15,16]. LIR has also attracted the attention of surgeons because this procedure is associated with earlier gastrointestinal recovery, shorter postoperative hospital stay, and lower complication rates[17,18]. However, CD is characterized by extensive intestinal inflammation and thickening of the mesentery and blood vessels, which pose

significant risks and difficulties in laparoscopic surgery[19]. Moreover, widespread inflammation can invade peripheral organs, such as the ureters, which can limit the application of minimally invasive surgery. Previous clinical studies have confirmed that laparoscopic resection in patients with ileocecal CD following failure of conventional therapy should be considered as a reasonable alternative[20]. The advantages of minimally invasive surgery for CD include reduced immune and inflammatory responses, fewer postoperative intestinal adhesions, less incision pain, and faster recovery[21,22]. Although laparoscopic techniques remain challenging in patients with
Wan J et al. Laparoscopic ileostomy reversal in Crohn’s disease

Figure 2 Long-term outcomes after ileostomy reversal. The reoperation rate after ileostomy reversal was similar between laparoscopic ileostomy reversal and open ileostomy reversal. LIR: Laparoscopic ileostomy reversal; OIR: Open ileostomy reversal.

CD, Bitner et al[3] reported that LIR was a safe and feasible option in 44 patients with CD after subtotal colectomy. However, larger studies are needed to confirm this claim. To date, LIR has been mainly applied for treatment of non-inflammatory diseases, such as colorectal cancer[23,24]. A study conducted by Russek et al[25] of 24 patients who underwent LIR found that the complication rate and surgical time were comparable to those of open surgery. In addition, extending the time to IR improved the patients’ nutritional status and allowed time for the adhesions to become less dense. A retrospective review of 133 patients demonstrated similar estimated blood loss, mean length of stay, and 30-d morbidity rates between LIR and OIR. Although the duration of LIR was longer, the additional procedures may provide long-term benefits[26].

To the best of our knowledge, this study is the first to evaluate the surgical approach and postoperative recovery of LIR for CD. In this study, cases of enterectomy during IR were excluded in order to compare OIR vs LIR alone. The results showed that postoperative recovery of patients with CD was better in the OIR group than the LIR group. This result is not difficult to explain. CD is a progressive disease resulting in fibrosis of the entire digestive tract. So, the entirety of the small intestine and colon can be explored during laparoscopic surgery, while only relatively small portions can be explored by open surgery. Also, in both LIR and OIR, incisions of the same length were made around the original ileostomy. Moreover, less minimally invasive instruments were used in OIR, so hospitalization costs were lower. In addition, laparoscopy is more convenient for the surgeon to dissociate the ileostoma from the abdominal cavity because of the good field of vision. Meanwhile, laparoscopy provides a clear field of vision of the entire gastrointestinal tract, which facilitates assessment of the remaining length of the healthy intestine, as well as the diseased portions. Therefore, laparoscopy greatly improves the rate of enterolysis and reduces the incidence of ileus. In this study, there was a significant difference in the rate of enterolysis between the IR and OIR groups (87.5% vs 41.7%, respectively, P < 0.05). In this regard, laparoscopy is undoubtedly beneficial to patients with CD. Hence, we continue to combine IR with enterectomy. The results of the present study showed that LIR did not increase the operative time, intraoperative blood loss, postoperative recovery time, length of hospitalization stay, hospitalization costs, or reoperation rate. Therefore, LIR is not a contraindication for patients with CD. In this study, 18 patients underwent enterectomy simultaneously with IR. In general, there are two main reasons for resection of the diseased intestinal segment at the same time of IR. First, ileostomy is often performed as an emergency surgery, as the diseased intestine can be removed at a later stage in the remission stage of CD. Second, during surgery for CD, excision of the intestine should be limited to avoid the occurrence of short bowel syndrome, as disease of the bowel can be alleviated with the use of biological agents. However, if drug treatment fails, simultaneous resection of the diseased bowel can be considered during IR.

Studies have shown that LIR with intracorporeal anastomosis was associated with shorter length of hospitalization without increasing overall costs[17]. A double-blind randomized controlled trial showed that intracorporeal anastomosis can reduce bowel manipulation and mesentery traction, which promotes quicker recovery of bowel function[27]. However, in the case of CD, extracorporeal anastomosis is preferred in
our center because CD is often accompanied by thickening of the mesentery and vasculature, thus hemostasis and reinforcing sutures are often required after anastomosis. These procedures will be safer and more reliable in vitro. In order to avoid anastomotic stoma-associated strictures in patients with CD, in addition to side-to-side anastomosis in digestive tract reconstruction, extracorporeal anastomosis can ensure the maximum size of the anastomotic stoma. For extracorporeal anastomosis, the length of the incision was not increased, which alleviated postoperative pain and improved satisfaction with the cosmetic result (Figure 1D-G).

CONCLUSION

LIR for CD is both safe and feasible. The short-term and long-term outcomes of LIR are comparable to those of OIR and do not prolong postoperative recovery. In view of the fact that this is a retrospective study with a small sample size, larger prospective trials are required to further confirm these findings.

ARTICLE HIGHLIGHTS

Research background
The advantages of minimally invasive surgery for ileostomy reversal (IR) have attracted increasing attention, although relatively few studies have investigated the benefits of IR for patients with Crohn’s disease (CD).

Research motivation
It is worthwhile to evaluate the potential benefits and risks of laparoscopy for patients with CD.

Research objectives
To compare the safety, feasibility, and short-term and long-term outcomes of laparoscopic IR (LIR) vs open IR (OIR) for treatment of CD.

Research methods
The baseline characteristics, operative data, and short-term (30-d) and long-term outcomes of patients with CD who underwent LIR and OIR between January 2017 and January 2020 were retrieved from an electronic database and retrospectively reviewed.

Research results
A total of 60 eligible patients were enrolled into the study, including 48 in the LIR group and 12 in the OIR group. There were no statistically significant differences in baseline characteristics, operative data, or short-term and long-term outcomes between the two groups. However, patients in the LIR group more frequently required lysis of adhesions as compared to those in the OIR group. Notably, following exclusion of patients who underwent enterectomy plus IR, OIR was more advantageous in terms of postoperative recovery of gastrointestinal function and hospitalization costs.

Research conclusions
The safety and feasibility of LIR for the treatment of CD are comparable to those of OIR with no increase in intraoperative or postoperative complications.

Research perspectives
LIR is feasible and safe for the treatment of CD patients with IR, and the short-term and long-term results are similar to those of OIR, thus further studies are warranted. In view of the fact that this is a retrospective study with a small sample size, larger prospective trials are required to further confirm these findings.
